Abstract

We study the nonlinear dynamics of a reaction-diffusion equation where the nonlinearity presents a discontinuity. We prove the upper semicontinuity of solutions and of the global attractor with respect to smooth approximations of the nonlinear term. We also give a complete description of the set of fixed points and study their stability. Finally, we analyze the existence of heteroclinic connections between the fixed points, obtaining information on the fine structure of the global attractor.

AMS Subject Classification: 35B40, 35B41, 35K55, 35K57, 37B25, 58C06

Keywords: reaction-diffusion equation, setvalued dynamical system, global attractor, upper semicontinuity, stability, heteroclinic connections

1 Introduction

In this paper we consider a reaction-diffusion equation having a discontinuous nonlinear term. The usual way to treat this kind of nonlinearities consists in joining the points in the discontinuity with a vertical line transforming the nonlinearity into a graph. Thus, the equation transforms into a differential inclusion instead of a differential equation. Equations of such a type appear in models of physical interest (see, for example, \cite{4}, \cite{16}, \cite{17}).

In particular, we are interested in the following equation

\begin{equation}
\begin{cases}
\frac{\partial u}{\partial t} - \Delta u + f(u) \in H_0(u) + \omega u, & \text{on } \Omega \times (0, T), \\
  u |_{\partial \Omega} = 0, \\
  u(x, 0) = u_0(x),
\end{cases}
\end{equation}

where $\Omega \subset \mathbb{R}^n$ is a bounded open subset with smooth boundary, $\omega \geq 0$, $f : \mathbb{R} \to \mathbb{R}$ is a continuous non-decreasing function, and

\begin{equation*}
H_0(u) = \begin{cases}
-1, & \text{if } u < 0, \\
[-1, 1], & \text{if } u = 0, \\
1, & \text{if } u > 0
\end{cases}
\end{equation*}
is the Heaviside function.

A natural and useful way for treating this inclusion consists in writing it in an abstract form by using subdifferential maps. We note that the multivalued map $H_0(u)$ is in fact the subdifferential of the absolute value $|u|$. Thus, the equation can be written as

$$\frac{du}{dt} + \partial \psi^1(u) - \partial \psi^2(u) \ni 0,$$

where $\partial \psi^i$ are some subdifferential maps defined below, see (2.1).

One important property of such equations is the lack of uniqueness of the Cauchy problem. Nevertheless, the asymptotic behavior and the qualitative properties of the solutions can be studied by using multivalued semiflows instead of semigroups (see [12]). The existence of a global compact connected attractor for such equations, under suitable conditions, is proved in [19], [20].

Our aim in this paper is twofold. On one hand, if we assume

$$\omega < \lambda_1,$$

where $\lambda_1$ is the first eigenvalue of $-\Delta$ in $H_0^1(\Omega)$, we approximate the nonlinear function $H_0$ by smooth ones $H_\varepsilon$ and study the convergence of the solutions and also of the global attractors. In this way we prove the upper semicontinuity of the global attractors of the approximations $A_\varepsilon$ with respect to the attractor of the original problem $A_0$, see Section 3.

The approximation of attractors for multivalued semiflows and differential inclusions has been studied before in [9], [10]. In [10] some types of approximations for differential inclusions with upper semicontinuous right-hand sides are studied, proving the upper (and in some cases lower) semicontinuity of the global attractor. However, the smooth approximations $H_\varepsilon$ that we consider in this paper are not included in any of the cases treated in [10].

On the other hand, we give a detailed description of the structure of the global attractor $A_0$ in the case where $f \equiv 0$ and $\omega = 0$ and the problem is one dimensional. In Section 4, we first prove that equation (1.1) has an infinite, but countable, number of equilibria $v_0 = 0$, $v_1^\pm$, $v_2^\pm$, ..., $v_k^\pm$, ..., which can be ordered using a natural energy (or Lyapunov function) $E(u)$, see Section 5:

$$E(v_1^+) = E(v_1^-) < E(v_2^+) = E(v_2^-) < ... < E(v_k^+) = E(v_k^-) < ... < E(v_0).$$

We prove then, in Section 6, that $v_1^\pm$ are asymptotically stable fixed points, and all the other ones are unstable. The fixed point $v \equiv 0$ possesses the following remarkable property: for any fixed point $v_k$ different from 0 there exists a solution, $u(t)$, with initial value $u(0) = 0$, such that $u(t)$ converges to $v_k$ as $t \to +\infty$. Note that the existence of a Lyapunov function implies that the global attractor can be described completely by the equilibria and the heteroclinic connections between them. The natural question is then to establish which connections actually exist. In the case of uniqueness of solutions, this question has already been studied for reaction–diffusion equations, see, for example, [5], [6], [13], [14].

In the present case, the attractors of the approximations, $A_\varepsilon$, correspond to a Chafee-Infante problem for which all existing connections are known, [8]. The natural conjecture is that the connections are the same when we pass to the limit case, that is, that a connection exists from the fixed point $v$ to the fixed point $v^*$ if $E(v) > E(v^*)$. Of course, since the energy is decreasing, no connections can exist if $E(v) \leq E(v^*)$. In fact, we will show that, in a sense, it is natural to expect that (1.1) is equivalent to a Chafee-Infante problem that has has undergo
all the typical bifurcation cascade of these type of problems, [7], and thus all connections should be present.

In Section 8, using the results on the approximation of the fixed points obtained in Section 7, we have given a partial answer to this question. In fact, we prove that a heteroclinic connection exists from \( v_0 \) to \( v_k^\pm, \forall k \geq 1 \), from \( v_k^\pm \) to \( v_{k-1}^\pm, \forall k \geq 2 \), and from \( v_k^\pm \) to \( v_1^\pm, \forall k \geq 1 \). Also, we have proved that, if there exists a connection from \( v_k^\pm \) to \( v_1^\pm, k > i \geq 1 \), then it can be replicated to a connection from \( v_{nk}^\pm \) to \( v_{ni}^\pm \), for all natural \( n \).

# 2 Preliminaries

Through the paper, we denote by \( || \cdot || \) the norm of the space \( L^2(\Omega) \). Note that (1.1) can be rewritten in the abstract form

\[
\begin{align*}
\frac{\partial u}{\partial t} + \partial \psi^1 (u) - \partial \psi^2 (u) &\geq 0, \\
u (0) &= u_0,
\end{align*}
\]

where \( \partial \psi^i, i = 1, 2 \), are the subdifferentials of the proper, convex, lower semicontinuous functions \( \psi^i : L^2(\Omega) \to ]-\infty, +\infty] \) (see [3]):

\[
\psi^1 (u) = \begin{cases} 
\frac{1}{2} \int_\Omega |\nabla u|^2 \, dx + \int_\Omega \int_0^u f (s) \, ds \, dx, & \text{if } u \in H^1_0 (\Omega), \int_0^u f (s) \, ds \in L^1 (\Omega), \\
+\infty, & \text{otherwise}
\end{cases}
\]

\[
D (\partial \psi^1) = \{ u \in H^2 (\Omega) \cap H^1_0 (\Omega) : f(u) \in L^2 (\Omega) \},
\]

\[
\partial \psi^1 (u) = -\Delta u + f(u),
\]

\[
\psi^2 (u) = \begin{cases} 
\int_\Omega \left( \omega \frac{u^2}{2} + \int_0^u H_0 (s) \, ds \right) \, dx, & \text{if } \int_0^u H_0 (s) \, ds \in L^1 (\Omega), \\
+\infty, & \text{otherwise}
\end{cases}
\]

\[
D (\partial \psi^2) = \{ u \in L^2 (\Omega) : \text{there exists } y \in L^2 (\Omega), y(x) \in H_0 (u(x)) + \omega u(x), \text{a.e. on } \Omega \}
\]

and

\[
\partial \psi^2 (u) = \{ y \in L^2 (\Omega), y(x) \in H_0 (u(x)) + \omega u(x), \text{a.e. on } \Omega \}.
\]

We note that \( \int_0^u H_0 (s) \, ds = |u| \). It is easy to see also that \( D (\partial \psi^2) = L^2 (\Omega) \).

**Definition 2.1** The function \( u(\cdot) \in C ([0, T], L^2(\Omega)) \) is called a strong solution of (2.1) if:

1. \( u(0) = u_0 \);
2. \( u(\cdot) \) is absolutely continuous on \( (0, T) \);
3. There exist a function \( g (t) \in \partial \psi^2 (u(t)), \text{a.e. on } (0, T), \) such that

\[
\frac{du(t)}{dt} - \Delta u + f(u) - g(t) = 0, \text{a.e. } t \in (0, T)
\]

or, alternatively,

\[
\frac{du(t)}{dt} - \Delta u + f(u) - h(t) = \omega u, \text{ a.e. } t \in (0, T),
\]

where, for a.e. \( t > 0, x \in \Omega, h(t, x) \in H_0 (u(t, x)), h(t, \cdot) \in L^2 (\Omega), \) and the equalities are understood in the sense of the space \( L^2 (\Omega) \).
For each $u_0 \in L^2(\Omega)$ and $T > 0$ there exists at least one strong solution $u(\cdot)$ of (1.1) such that $g(\cdot) \in L^2(0,T;L^2(\Omega))$. Note that in fact $h \in L^\infty(0,T;L^\infty(\Omega))$ and that this is true for any solution such that $h(t)$ is measurable. Each solution can be extended to the whole semiline $t \geq 0$, so that they are global. Let $\mathcal{D}(u_0)$ be the set of all strong solutions defined on $[0, +\infty)$ and such that $g(\cdot) \in L^2_{\text{loc}}(0,T;L^2(\Omega))$. Then the multivalued map into the parts of $L^2(\Omega)$, $G_0 : \mathbb{R}_+ \times L^2(\Omega) \to P(L^2(\Omega))$,

$$G_0(t, u_0) = \bigcup_{u \in \mathcal{D}(u_0)} u(t)$$

is a strict multivalued semiflow, that is, for any $t_i \geq 0$, $i = 1, 2$, $G_0(t_1 + t_2, u_0) = G_0(t_2, G_0(t_1, u_0))$ and $G_0(0, \cdot) = Id$. Moreover, the set $G_0(t, u_0)$ is compact and the semiflow is upper semicontinuous, that is

$$\text{dist} (G_0(t, y_k), G_0(t, y)) \to 0, \quad \text{if} \quad y_k \to y.$$ 

See [19, Theorem 4, Lemmas 1, 2 and 6] for the proof of these facts.

Let us consider the problem

$$\begin{cases}
\frac{du}{dt} - \Delta u + f(u) = l(t), \\
u(0) = u_0 \in L^2(\Omega).
\end{cases} \tag{2.4}$$

It is clear that any $u \in \mathcal{D}(u_0)$ is a strong solution of (2.4) with $l = g$. We shall need the following regularity result, see e.g. [3, p.189].

**Proposition 2.2** For any $l(\cdot) \in L^2(0,T;L^2(\Omega))$, $u_0 \in L^2(\Omega)$, there exists a unique strong solution of inclusion (2.4) such that

$$u(\cdot) \in C([0,T], L^2(\Omega)), \sqrt{t} \frac{du}{dt} \in L^2(0,T;L^2(\Omega)), \psi^1(u(\cdot)) \in L^1(0,T),$$

and $\psi^1(u(t))$ is absolutely continuous on $[\delta, T]$, for all $\delta > 0$.

If $u_0 \in D(\psi^1)$, then $\frac{du}{dt} \in L^2(0,T;L^2(\Omega))$ and $\psi^1(u) \in L^\infty(0,T)$. If $u_0, v_0 \in L^2(\Omega)$, then

$$\|u(t) - v(t)\| \leq \|u_0 - v_0\|, \quad \text{for all} \ t \in [0,T].$$

**Remark 2.3** Note that, from comparison arguments, if $f(0) \leq 1$ then if $u_0 \geq 0$ in $\Omega$ then there exists a solution of (1.1) which satisfies

$$\frac{du}{dt}(t) - \Delta u + f(u) = 1 + \omega u,$$

since 0 is a subsolution. On the other hand, if $f(0) \leq -1$, since we can compare solutions of (2.3) from below with

$$\frac{du}{dt}(t) - \Delta u + f(u) = -1 + \omega u,$$

we have that the solution of (1.1) is unique an strictly positive for $t > 0$.

Analogous results can be derived for $u_0 \leq 0$, if $f(0) \geq -1$ and $f(0) \geq 1$ respectively.
The set \( A \) is called a global attractor for the multivalued semiflow \( G_0 \) if it attracts any bounded subset \( B \) of \( L^2(\Omega) \), i.e.

\[
dist(G_0(t,B) , A) \to 0, \text{ as } t \to +\infty,
\]

where \( dist(C, A) = \sup_{c \in C} \inf_{a \in A} \|c - a\| \) is the Hausdorff semidistance, and it is negatively semi-invariant, i.e.

\[
A \subset G_0(t, A) , \text{ for all } t \geq 0.
\]

Note that since \( f \) is monotone, we have \((f(s) - f(0))s \geq 0 \) for all \( s \in \mathbb{R} \). Hence we have, for every \( y_2 \in H_0(s), s \in \mathbb{R} \)

\[
-f(s)s + y_2s + \omega s^2 \leq \omega s^2 + D|s|,
\]

with \( D = \|f(0)\| + 1 \). Hence if we assume

\[
\omega < \lambda_1,
\]

where \( \lambda_1 \) is the first eigenvalue of \(-\Delta \) in \( H^1_0(\Omega) \), then the results in [19, Theorem 4] prove that \( G_0 \) has the global compact invariant (i.e. \( A = G_0(t, A), \forall t \geq 0 \)) attractor \( A \). Moreover, \( A \) is a connected set [20]. See [1] for the case of singled–valued equations and Corollary 3.2 below.

### 3 Upper semicontinuity of the global attractor

Let us consider now a parameterized non-decreasing family of functions \( H_\varepsilon \in C^1(\mathbb{R}), \varepsilon > 0 \), such that

\[
|H_\varepsilon(s) - H_0(s)| < \varepsilon, \text{ if } |s| > \varepsilon,
\]

\[-1 < H_\varepsilon(s) < 1, \text{ for all } s,
\]

and such that \( H'_\varepsilon \) is non-increasing for \( u \geq 0 \), and non-decreasing for \( u \leq 0 \). It follows from these conditions that

\[
dist(Graph(H_\varepsilon), Graph(H_0)) \leq \varepsilon,
\]

and also that \( |H'_\varepsilon(s)| \leq C_\varepsilon \), for all \( s \).

We consider the equation

\[
\begin{cases}
\frac{\partial u_\varepsilon}{\partial t} - \Delta u_\varepsilon + f(u_\varepsilon) - H_\varepsilon(u_\varepsilon) = \omega u_\varepsilon, \\
u_\varepsilon|_{\partial\Omega} = 0, \\
u_\varepsilon(0) = u_0.
\end{cases}
\]

We note that the boundedness of \( H'_\varepsilon \) implies that \( f(u) - H_\varepsilon(u) = f_\varepsilon(u) - \omega_\varepsilon u \), for some \( \omega_\varepsilon \geq 0 \) and a non-decreasing continuous map \( f_\varepsilon \). Then (3.2) has a unique strong solution \( u_\varepsilon(\cdot) \) for any \( u_0 \in L^2(\Omega) \) (see [3, p.189]). Hence, it defines a semigroup \( G_\varepsilon : \mathbb{R}^+ \times L^2(\Omega) \to L^2(\Omega) \).

Now we derive suitable uniform estimates on the solutions of (1.1) and (3.2), which will be used below. To accomplish this, note first that, analogously to (2.5), we have

\[
-f(s)s + H_\varepsilon(s)s + \omega s^2 \leq \omega s^2 + D|s|
\]

with \( D = \|f(0)\| + 1 \), independent of \( \varepsilon \).

Then we have the following result. Note that in the estimates below, when we refer to solutions of (1.1) we mean that the estimates are valid for all strong solutions in \( \mathcal{D}(u_0) \), that is, for the multivalued semiflow \( G_0 \).

5
Theorem 3.1  With the assumptions above, assume furthermore (2.6) holds true.

Let \( 0 \leq \phi \in L^\infty(\Omega) \) be the unique solution of
\[
\begin{aligned}
-\Delta \phi &= \omega \phi + D \quad \text{in } \Omega \\
\phi &= 0 \quad \text{on } \Gamma.
\end{aligned}
\]

and let \( u_0 \in B \subset L^2(\Omega) \) a bounded set of initial data in (3.2).

Then if \( u \) denotes either a solution of (1.1) or (3.2) then we have:
i) For \( t \geq 0 \)
\[
\|u(t)\| \leq C(B, t) + \|\phi\|
\]
for some bounded, independent of \( \varepsilon \), decreasing function \( C(B, t) \to 0 \) as \( t \to \infty \).

ii) For \( t \geq 1 \)
\[
\|u(t)\|_{L^\infty(\Omega)} \leq C(B, t) + \|\phi\|_{L^\infty(\Omega)}
\]
for some bounded, independent of \( \varepsilon \), decreasing function \( C(B, t) \to 0 \) as \( t \to \infty \). Even more
\[
\limsup_{t \to \infty} |u(t, x, u_0)| \leq \phi(x), \quad \text{uniformly in } x \in \Omega
\]
and the limit above is uniform for \( u_0 \in B \). Moreover, if \( |u_0(x)| \leq \phi(x) \) for all \( x \in \Omega \), then \( |u(t, x, u_0)| \leq \phi(x) \) for all \( x \in \Omega \) and \( t \geq 0 \).

In particular the ball in \( L^\infty(\Omega) \) of radius \( \|\phi\|_{L^\infty(\Omega)} + 1 \) is absorbing for (1.1) and (3.2). In the latter case, the entering time is independent of \( \varepsilon \).

iii) For every \( 1 \leq p < \infty \), \( \delta > 0 \) and \( t \geq 1 \)
\[
\|u(t)\|_{W^{2-\delta, p}(\Omega)} \leq C(B, \phi, t)
\]
for some bounded, independent of \( \varepsilon \), decreasing function \( C(B, \phi, t) \to C(\phi) \) as \( t \to \infty \).

Proof. We begin with the case of (3.2). Hence, from (3.3) and by standard comparison arguments we have that
\[
|u_\varepsilon(t, x)| \leq U(t, x)
\]
where \( U \) is a solution of the linear problem
\[
\begin{aligned}
\frac{\partial U}{\partial t} - \Delta U &= \omega U + D, \\
U \big|_{\partial \Omega} &= 0, \\
U(0) &= |u_\varepsilon|.
\end{aligned}
\]

(3.4)

Hence, \( U \) can be written as \( U = z + \phi \) where
\[
\begin{aligned}
\frac{\partial z}{\partial t} - \Delta z &= \omega z, \\
z \big|_{\partial \Omega} &= 0, \\
z(0) &= |u_0| - \phi.
\end{aligned}
\]

Thus, by standard smoothing estimates of the heat equation we have
\[
\|z(t)\|_{L^\infty(\Omega)} \leq C \frac{e^{-at}}{t^{N/2}} \|z(0)\|_{L^2(\Omega)}
\]
with $\alpha = \lambda_1 - \omega > 0$, since we assume (2.6). This and the fact that the heat equation preserves the sign of $z(0)$ concludes part i).

For part ii) notice that from (3.2) and the bounds above, we have that for $t \geq 1$,

$$\frac{\partial u_\varepsilon}{\partial t} - \Delta u_\varepsilon = h_\varepsilon(x, t)$$

with $h_\varepsilon(x, t) = -f(u_\varepsilon) + H_\varepsilon(u_\varepsilon) + \omega u_\varepsilon \in L^\infty(1, \infty; L^\infty(\Omega))$ and

$$\|h_\varepsilon\|_{L^\infty(\Omega)} \leq C_0(B, \phi, t)$$

for some function $C_0(B, \phi, t)$ as in the statement. Therefore, parabolic regularity gives the result.

Finally, for the solutions of (1.1) note that according to Definition 2.1 and (2.5), we have

$$|u(t, x)| \leq U(t, x)$$

as well. Hence the same arguments as before conclude. ■

As a consequence we get the following result.

**Corollary 3.2**

Assume $\varepsilon_0 > 0, 1 \leq p < \infty$ and $\delta > 0$. Then

i) For any bounded set $B \subset L^2(\Omega)$, the set

$$\bigcup_{0 \leq \varepsilon \leq \varepsilon_0} \{G_\varepsilon(t, B), \ t \geq 0\} \subset L^2(\Omega)$$

is bounded in $L^2(\Omega)$.

ii) For any bounded set $B \subset L^2(\Omega)$, the set

$$\bigcup_{0 \leq \varepsilon \leq \varepsilon_0} \{G_\varepsilon(t, B), \ t \geq 1\} \subset W^{2-\delta,p}(\Omega)$$

is precompact in $W^{2-\delta,p}(\Omega)$.

iii) There exists an absorbing ball for (1.1) and (3.2) in $W^{2-\delta,p}(\Omega)$. In particular (3.2) has a compact invariant attractor $A_\varepsilon$ in $L^2(\Omega)$.

The attractors $A_\varepsilon$ for (3.2) and $A_0$ for (1.1) attract bounded sets of $L^2(\Omega)$ in the norm of $W^{2-\delta,p}(\Omega)$.

iv) The union of the attractors

$$\bigcup_{0 \leq \varepsilon \leq \varepsilon_0} A_\varepsilon \subset W^{2-\delta,p}(\Omega)$$

is precompact in $W^{2-\delta,p}(\Omega)$.

**Remark 3.3** Note that in both Theorem 3.1 and Corollary 3.2 the results remain true if we take $t \geq t_0$, for any $t_0 > 0$, instead of $t \geq 1$.

Now we prove a result on the continuity of the semiflows as $\varepsilon \to 0$. 

7
Theorem 3.4 Assume $1 \leq p < \infty$ and $\delta > 0$ and let (2.6) hold.

Then for any $t > 0$ and any compact set $K \subset L^2(\Omega)$ we have

$$\text{dist} \,(G_\varepsilon(t,K),G_0(t,K)) \to 0, \text{ as } \varepsilon \to 0,$$

where the distance is taken in the norm of $W^{2-\delta,p}(\Omega)$.

If $u_{\varepsilon,0} \to u_0$ in $L^2(\Omega)$ as $\varepsilon \to 0$, then for any $T > 0$ there exists a subsequence $\varepsilon_n$ such that $u_{\varepsilon_n}$ converges to some $u \in D(u_0)$ in $C([0,T], L^2(\Omega))$.

Proof. Note that it is enough to prove the result for the distance in $L^2(\Omega)$. Once this is done, the compactness results in Corollary 3.2 above conclude.

Suppose the opposite, that is, there exist $\delta > 0$, $\varepsilon_n \to 0$ and $u_{0_n} \in K$ such that

$$\text{dist} \,(G_{\varepsilon_n}(t,u_{0_n}(t)),G_0(t,K)) > \delta, \text{ for all } n.$$

Let $u_n(t) = G_{\varepsilon_n}(t,u_{0_n}(t))$. Define the sequences $g_n(t) = H_{\varepsilon_n}(u_n(t)) + \omega u_n(t)$ and $h_n(t) = H_{\varepsilon_n}(u_n(t))$. Note that from point i) in Theorem 3.1 it follows that

$$\|u_n(t)\| \leq C_0, \text{ for all } t \geq 0,$$

so that

$$\|g_n(t)\| \leq C_1 + \omega \|u_n(t)\| \leq C_2, \text{ for a.e. } t \geq 0.$$

Also, using similar arguments as in [19, p.722] one can prove that

$$\left\|\sqrt{t} \frac{du_n}{dt}\right\|_{L^2(0,T;L^2(\Omega))} \leq C_3.$$

Hence, there exists a subsequence, that we still denote the same, such that $u_n \to u$ and $\sqrt{t} \frac{du_n}{dt} \to \sqrt{t} \frac{du}{dt}$ weakly in $L^2(0,T;L^2(\Omega))$. Moreover, Ascoli-Arzelà theorem implies that for any fixed $M > 0$ we have $u_n \to u$ in $C\left([\frac{1}{M},T], L^2(\Omega)\right)$ and $u$ is absolutely continuous on $\left[\frac{1}{M},T\right]$. Furthermore, the compactness results in Corollary 3.2 imply that $u_n \to u$ in $C\left([\frac{1}{M},T], L^\infty(\Omega) \cap H^1_0(\Omega)\right)$.

Also, note that $g_n = h_n + \omega u_n$ converges to some $g = h + \omega u \in L^\infty(0,T;L^2(\Omega))$ weakly star in $L^\infty(0,T;L^2(\Omega))$ and weakly in $L^2(0,T;L^2(\Omega))$, where $h \in L^\infty(0,T;L^\infty(\Omega))$. On the other hand, since $-\Delta u_n + f(u_n) = -\frac{du_n}{dt} + g_n$, then $\sqrt{t} \left(-\Delta u_n + f(u_n)\right)$ converges to $l(t) = \sqrt{t} \left(-\frac{du}{dt} + g\right)$ weakly in $L^2(0,T;L^2(\Omega))$. Finally, the convergence for $u_n$ above implies that $f(u_n) \to f(u)$ in $C\left([\frac{1}{M},T], L^\infty(\Omega)\right)$. Hence, we find at once that $u$ satisfies

$$\frac{du}{dt} - \Delta u(t) + f(u(t)) = g(t) = h(t) + \omega u, \text{ a.e. on } (0,T).$$

Now, we show that $h(t) \in H_0(u(t))$, a.e. in $(0,T)$. For this we shall prove first that for a.e. $x \in \Omega$ and $s \in (0,T)$

$$\text{dist} \,(h_n(s,x),H_0(u(s,x))) \to 0, \text{ as } n \to \infty.$$
Indeed, if \( u(s, x) = 0 \), then \( h_n(s, x) = H_{\varepsilon_n}(u_n(s, x)) \in [-1, 1] = H_0(u(s, x)), \forall n \), so that the result is evident. If \( u(s, x) < 0 \), then
\[
\text{dist}(h_n(s, x), H_0(u(s, x))) = |H_{\varepsilon_n}(u_n(s, x)) + 1| \to 0, \text{ as } n \to \infty.
\]

Finally, if \( u(s, x) > 0 \), then
\[
\text{dist}(h_n(s, x), H_0(u(s, x))) = |H_{\varepsilon_n}(u_n(s, x)) - 1| \to 0, \text{ as } n \to \infty.
\]

Now, Proposition 1.1 in [18] implies that for a.e. \( t \in (0, T) \)
\[
h(t) \in \cap_{n \geq 0} \overline{co} \bigcup_{k \geq n} h_k(t).
\]

Then \( h(t) = \lim_{n \to \infty} y_n(t) \) strongly in \( L^2(\Omega) \), where \( y_n(t) = \sum_{i=1}^{M} \lambda_i h_{k_i}(t), \sum_{i=1}^{M} \lambda_i = 1, k_i \geq n \). We note that for any \( t \in [0, T] \) and a.e. \( x \in \Omega \), we can find \( \varepsilon(x, t) < 1 \) such that if \( k \geq n \), then \( \text{dist}(h_k(t, x), H_0(u(t, x))) \leq \varepsilon \). Therefore,
\[
\text{dist}(y_n(t, x), H_0(u(t, x))) \leq \sum_{i=1}^{M} \lambda_i \text{dist}(h_{k_i}(t, x), H_0(u(t, x))) \leq \varepsilon.
\]

Hence, since we can assume that for a.e. \((t, x) \in (0, T) \times \Omega\), \( y_n(t, x) \to h(t, x) \), it follows that \( h(t, x) \in H_0(u(t, x)) \).

It remains to check that \( u \) is continuous as \( t \to 0^+ \). Let \( \hat{u} \) be the unique solution of
\[
\begin{cases}
\frac{du}{dt} - \Delta u + f(u) = \omega u, \\
\quad u|_{\partial \Omega} = 0, \\
\quad u(0) = u_0,
\end{cases}
\]
and let \( v_n(t) = u_n(t) - \hat{u}(t) \). In a standard way, using that \( f \) is monotone, we can prove that
\[
\frac{d}{dt} ||v_n||^2 \leq K_1 + K_2 ||v_n||^2 \leq K,
\]
so that
\[
||v_n(t)||^2 \leq ||v_n(0)||^2 + Kt = Kt.
\]
Hence, \( ||u(t) - \hat{u}(t)||^2 = \lim_{n \to \infty} ||v_n(t)||^2 \leq Kt \), for \( t > 0 \), and
\[
||u(t) - u_0|| \leq ||u(t) - \hat{u}(t)|| + ||\hat{u}(t) - u_0|| < \delta,
\]
as soon as \( t < \varepsilon(\delta) \).

We have proved that \( u(\cdot) \) is a strong solution of (1.1). Since \( u_n(t) \to u(t) \in G_a(t, K) \) we have obtained a contradiction. Note that at the same time we have established the second statement. ■

Now we are ready to prove the following result on the uppersemicontinuity of the attractors

**Theorem 3.5** Assume \( 1 \leq p < \infty \) and \( \delta > 0 \) and let (2.6) hold.
Then \( \text{dist}(A_\varepsilon, A_0) \to 0 \), as \( \varepsilon \to 0 \) where the distance is taken in the norm of \( W^{2-\delta, p}(\Omega) \).
Proof. Let $\eta > 0$ be fixed and $\varepsilon_0$ sufficiently small. Then for sufficiently large $T$ we have

$$\text{dist} \left( G_0(T, \bigcup_{0 \leq \varepsilon \leq \varepsilon_0} \mathcal{A}_\varepsilon), \mathcal{A}_0 \right) \leq \eta/2.$$ 

Now from Theorem 3.4, we have, for sufficiently small $\varepsilon_0$

$$\text{dist} \left( G_\varepsilon(T, \bigcup_{0 \leq \varepsilon \leq \varepsilon_0} \mathcal{A}_\varepsilon), G_0(T, \bigcup_{0 \leq \varepsilon \leq \varepsilon_0} \mathcal{A}_\varepsilon) \right) \leq \eta/2.$$ 

Hence, by the triangle inequality, we get

$$\text{dist} \left( \mathcal{A}_\varepsilon, \mathcal{A}_0 \right) \leq \text{dist} \left( G_\varepsilon(T, \bigcup_{0 \leq \varepsilon \leq \varepsilon_0} \mathcal{A}_\varepsilon), G_0(T, \bigcup_{0 \leq \varepsilon \leq \varepsilon_0} \mathcal{A}_\varepsilon) \right) \leq \eta.$$ 

\[ \square \]

As a consequence of the last theorem and Corollary 3.2, we shall prove the convergence of the approximations in the space $C([0, T], W^{2-\delta,p}(\Omega))$.

**Corollary 3.6** If $u_{\varepsilon_0} \rightarrow u_0$ in $L^2(\Omega)$, where $u_{\varepsilon_0} \in \mathcal{A}_\varepsilon$, $u_0 \in \mathcal{A}$, then for any $T > 0$ there exists a subsequence $\varepsilon_n$ such that $u_n$ converges to some $u \in \mathcal{D}(u_0)$ in $C([0, T], W^{2-\delta,p}(\Omega))$, $1 \leq p < \infty, \delta > 0$.

**Proof.** We know from Theorem 3.4 that there exists a subsequence such that $u_{\varepsilon_n} \rightarrow u \in \mathcal{D}(u_0)$ in $C([0, T], L^2(\Omega))$. Then the results follows from the fact that, in view of Corollary 3.2, $\bigcup_{0 \leq \varepsilon \leq \varepsilon_0} \mathcal{A}_\varepsilon$ is precompact in $W^{2-\delta,p}(\Omega)$.

\[ \square \]

4 Fixed points

From now on we will consider equation (1.1) with $n = 1$, $\Omega = (0, 1)$ and $f \equiv 0$, which reads

$$\left\{ \begin{array}{ll}
\frac{\partial u}{\partial t} - \frac{\partial^2 u}{\partial x^2} - H_0(u) \ni \omega u, & \text{on } (0, 1) \times (0, T), \\
u(0, t) = u(1, t) = 0, \\
u(x, 0) = u_0(x).
\end{array} \right. \tag{4.1}$$

We shall assume in the sequel that $0 \leq \omega < \pi^2$. We note that the last condition implies that the global attractor exists (see Section 2).

Our aim is to give a complete description of the set of fixed points in this particular case. A fixed point (stationary point or equilibria) is a constant in time solution $v$. It is clear from the definition of a strong solution that $v$ satisfies $-\frac{\partial^2 v}{\partial x^2} = \xi + \omega v$, where $\xi \in L^2(0, 1)$ and $\xi(x) \in H_0^1(v(x))$ for a.e. $x \in (0, 1)$. We note also that $v \in H^2(0, 1) \cap H_0^1(0, 1)$, and then $v, v'$ are absolutely continuous on $[0, 1]$, [3].
First let \( \omega = 0 \). The fixed points \( v(x) \) satisfy the system

\[
\begin{align*}
  y' &\in -H_0(v), \\
  v' &= y, \\
  v(0) &= v(1) = 0.
\end{align*}
\]

The solution of system (4.2) is \( y^2 + 2|v| = C \), which gives us two families of parabolic functions. Obviously, \( v_0 = 0 \) is a fixed point. We note that \( v(x) \) satisfies

\[
\begin{align*}
v'' &= -1, \text{ if } v > 0, \\
v'' &= 1, \text{ if } v < 0.
\end{align*}
\]

Then

\[
\begin{align*}
v(x) &= -\frac{x^2}{2} + Bx + D, \text{ if } v > 0, \\
v(x) &= \frac{x^2}{2} + B'x + D', \text{ if } v < 0.
\end{align*}
\]

We note that if (4.3)-(4.4) are local solutions such that \( v(0) = 0 \), then \( D = D' = 0 \). Further, we need to satisfy \( v(1) = 0 \). If we consider the case \( v > 0 \), then the “time” for going from the initial point \((v(0), y(0)) = (0, \sqrt{C})\) to the point \((\frac{1}{2}, 0)\), that is a quarter loop, is \( T = \int_0^C \frac{du}{\sqrt{C - 2u}} = \sqrt{C} \). By symmetry the “time” for going from the initial point \((v(0), y(0)) = (0, \sqrt{C})\) to the point \((0, -\sqrt{C})\), that is a half loop, is \( T_0 = 2T = 2\sqrt{C} \). The case \( v < 0 \) is identical. In order to satisfy the boundary conditions in (4.2) we need that either \((v(1), y(1)) = (0, \sqrt{C})\) or \((v(1), y(1)) = (0, -\sqrt{C})\). Concatenating the functions (4.3)-(4.4) we obtain solutions of (4.2) if \( T_0 = \frac{1}{n} \) for any \( n \geq 1 \), that is, if \( C = C_n = \frac{1}{4n^2} \). We can easily check that these solution belong to \( H^2(0, 1) \cap H^1_0(0, 1) \) and then are strong solutions of (4.2). Hence there exists an infinite number of fixed points. We note also that if \( v_+^n \) (respectively \( v_-^n \)) is a fixed point such that \( v'(0) > 0 \) (respectively \( v'(0) < 0 \)) and \( C_n = \frac{1}{4n^2} \), then \( v_+^n \left(\frac{1}{n}\right) = 0 \) (respectively \( v_-^n \left(\frac{1}{n}\right) = 0 \)), so that in the interval \([0, \frac{1}{n}]\) the functions \( v_+^n, v_-^n \) are given by (4.3)-(4.4) with \( B = \frac{1}{2n}, D = 0 \) (respectively \( B' = -\frac{1}{2n}, D' = 0 \)). Finally, we obtain the following fixed points:

\[
\begin{align*}
v_0 &= 0, \\
v_1^+(x) &= -\frac{x^2}{2} + \frac{x}{2}, \quad v_1^-(x) = -v_1^+(x) \\
v_2^+(x) &= \begin{cases} 
-\frac{x^2}{2} + \frac{x}{4}, & \text{if } 0 \leq x \leq \frac{1}{2}, \\
\frac{x-\frac{1}{2}}{2} & -\frac{x-\frac{1}{2}}{4}, & \text{if } \frac{1}{2} \leq x \leq 1 
\end{cases}, \quad v_2^-(x) = -v_2^+(x) \\
&\vdots \\
v_n^+(x) &= \begin{cases} 
-\frac{x^2}{2} + \frac{x}{2n}, & \text{if } 0 \leq x \leq \frac{1}{n}, \\
\frac{x-\frac{1}{2}}{2} & -\frac{x-\frac{1}{2}}{2n}, & \text{if } \frac{k}{n} \leq x \leq \frac{k+1}{n}, k \text{ is even}, \\
\frac{x-\frac{1}{2}}{n} & -\frac{x-\frac{1}{2}}{2n}, & \text{if } \frac{k}{n} \leq x \leq \frac{k+1}{n}, k \text{ is odd}, \\
k = 0, \ldots, n - 1
\end{cases} \\
v_n^-(x) &= \begin{cases} 
-(x-\frac{1}{2})^2 + \frac{x-\frac{1}{2}}{2n}, & \text{if } 0 \leq x \leq \frac{1}{n}, k \text{ is even}, \\
\frac{(x-\frac{1}{2})^2}{n} & -\frac{(x-\frac{1}{2})^2}{2n}, & \text{if } \frac{k}{n} \leq x \leq \frac{k+1}{n}, k \text{ is odd}, \\
k = 0, \ldots, n - 1
\end{cases}
\end{align*}
\]

Next we ensure that there are no other fixed points.
Lemma 4.1 For any \((v_0, y_0) \in \mathbb{R}^2\) the Cauchy problem
\[
\begin{cases}
y' = -H_0(v) \\
v' = y \quad v(0) = v_0, y(0) = y_0
\end{cases}
\] (4.5)
has a unique strong solution in some interval \([0, \delta]\).

Proof. By a strong solution we mean an absolutely continuous function \((v(x), y(x))\) satisfying (4.5) for a.e. \(x \in [0, \delta]\). The existence is clear from the previous results, so that we prove only the uniqueness.

Consider first the case where \((v_0, y_0) \neq (0, 0)\). If \(v_0 \neq 0\) (say \(v_0 > 0\)) and \(v_1, v_2\) are two solutions, then the continuity of any solution implies the existence of an interval \([0, \delta]\) such that \(v_i(x) > 0\), for \(x \in [0, \delta]\). In such a case \(H_0(v_i(x)) = 1\), so that \((y_1 - y_2)' = 0\) and then \(y_1 = y_2\) on \([0, \delta]\). Hence, \((v_1 - v_2)' = 0\) and \(v_1 = v_2\) on \([0, \delta]\). If \(v_0 = 0, y_0 \neq 0\) (say \(y_0 > 0\)) and \(v_1, v_2\) are two solutions, then the continuity of \(y_i\) gives \(y_i(x) > 0\) on some \([0, \delta]\). Since \(v'_i = y_i\), this implies that \(v_i(x) > 0\) on \((0, \delta]\), and now we argue as before to obtain \(v_1 = v_2\) on \([0, \delta]\).

Finally, let \((v_0, y_0) = (0, 0)\). Let \(v(x)\) be a solution not equal to \(v_0 \equiv 0\). Then in some interval \((0, \delta]\) we have either \(v(x) > 0\) or \(v(x) < 0\). If, say, \(v(x) > 0\), then \(H_0(v(x)) = 1\) and \(v'' = -1\). Hence, \(v(x) = -\frac{x^2}{2} < 0\) on \([0, \delta]\), which is a contradiction. A similar argument is valid for \(v(x) < 0\).

Remark 4.2 We have proved that there exists an infinite but countable number of fixed points and have found them explicitly. We note also that the fixed points \(v^+_n, v^-_n\) have exactly \(n - 1\) zeros on \((0, 1)\).

Next we observe the following self-similarity property of the solutions. We note that if take \(v^+_1\) and define the function
\[
v(x) = \begin{cases} 
\frac{1}{4} v^+_1(2x), & x \in [0, \frac{1}{2}], \\
-\frac{1}{4} v^+_1(2(x - \frac{1}{2})), & x \in [\frac{1}{2}, 1],
\end{cases}
\]
then \(v(x) = v^+_2(x)\). In the same way we have that for any \(v^+_k, k \geq 1\), and \(n\) we have
\[
v^+_nk(x) = \begin{cases} 
\frac{1}{n} v^+_k(nx), & x \in [0, \frac{1}{n}], \\
-\frac{1}{n} v^+_k(n(x - \frac{1}{n})), & x \in \left[\frac{1}{n}, \frac{2}{n}\right], \\
\vdots
\end{cases}
\]

The case \(0 < \omega < \pi^2\) is rather similar and we omit the details. In this case the fixed points
are the following:
\[ v_0 \equiv 0 \]
\[ v_1^+ (x) = \frac{1}{\omega} \cos (\sqrt{\omega} x) + \frac{1 - \cos (\sqrt{\omega})}{\omega \sin (\sqrt{\omega})} \sin (\sqrt{\omega} x) - \frac{1}{\omega}, \]
\[ v_1^- (x) = -v_1^+ (x) \]
\[ v_2^+ (x) = \begin{cases} 
\frac{1}{\omega} \cos (\sqrt{\omega} x) + \frac{1 - \cos (\sqrt{\omega})}{\omega \sin (\sqrt{\omega})} \sin (\sqrt{\omega} x) - \frac{1}{\omega}, & \text{if } 0 \leq x \leq \frac{1}{2}, \\
-\frac{1}{\omega} \cos (\sqrt{\omega} (x - \frac{1}{2})) - \frac{1 - \cos (\sqrt{\omega})}{\omega \sin (\sqrt{\omega})} \sin (\sqrt{\omega} (x - \frac{1}{2})) + \frac{1}{\omega}, & \text{if } \frac{1}{2} \leq x \leq 1, 
\end{cases} \]
\[ v_2^- (x) = -v_2^+ (x) \]
\[ v_n^+ (x) = \begin{cases} 
\frac{1}{\omega} \cos (\sqrt{\omega} x) + \frac{1 - \cos (\sqrt{\omega})}{\omega \sin (\sqrt{\omega})} \sin (\sqrt{\omega} x) - \frac{1}{\omega}, & \text{if } 0 \leq x \leq \frac{1}{n}, \\
\vdots \\
\frac{1}{\omega} \cos (\sqrt{\omega} (x - \frac{k}{n})) + \frac{1 - \cos (\sqrt{\omega})}{\omega \sin (\sqrt{\omega})} \sin (\sqrt{\omega} (x - \frac{k}{n})) - \frac{1}{\omega}, & \text{if } \frac{k}{n} \leq x \leq \frac{k+1}{n}, k \text{ is even}, \\
-\frac{1}{\omega} \cos (\sqrt{\omega} (x - \frac{k}{n})) - \frac{1 - \cos (\sqrt{\omega})}{\omega \sin (\sqrt{\omega})} \sin (\sqrt{\omega} (x - \frac{k}{n})) + \frac{1}{\omega}, & \text{if } \frac{k}{n} \leq x \leq \frac{k+1}{n}, k \text{ is odd}, \\
& k = 0, \ldots, n-1 
\end{cases} \]
\[ v_n^- (x) = -v_n^+ (x) \]

Remark 4.3 Observe that for each \( n \in \mathbb{N} \), in the interval \( \frac{k}{n} \leq x \leq \frac{k+1}{n}, k = 0, \ldots, n-1 \), \( v_n^+ \) is the unique solution of
\[
\begin{align*}
-\frac{\partial^2 u}{\partial x^2} &= (-1)^k + \omega u, \\
\big| u \big( \frac{k}{n} \big) \big| &= u \big( \frac{k+1}{n} \big) = 0
\end{align*}
\]
and \( v_n^- (x) = -v_n^+ (x) \). Hence its sign is given by \((-1)^k\).

Also, note that, for example \( v_2^+ \) satisfies \( v(x) = -v \left( x - \frac{1}{2} \right) = -v \left( 1 - x \right) \), for \( x \in \left[ \frac{1}{2}, 1 \right] \), with analogous symmetries for the other equilibria.

 Remark 4.4 We note that when \( \omega \) approaches and crosses the value \( \pi^2 \) the fixed points \( v_n^\pm \) suffer a bifurcation to infinity and disappear. The same occurs for \( v_2^\pm \) when \( \omega \) cross \( 4\pi^2 \), for \( v_3^\pm \) when \( \omega \) cross \( 9\pi^2 \), etc.

5 A Lyapunov function

Let us define the continuous function \( E : H_0^1 (0, 1) \to \mathbb{R} \) by
\[
E (u) = \frac{1}{2} \int_0^1 \left| \frac{\partial u}{\partial x} \right|^2 dx - \int_0^1 \left( |u| + \frac{\omega}{2} u^2 \right) dx = \psi^1 (u) - \psi^2 (u). \tag{5.1}
\]

Let \( u(t) \) be an arbitrary solution of inclusion (4.1). We note that by the regularity of the solutions, Proposition 2.2, \( E (u(t)) : (0, +\infty) \to \mathbb{R} \) is a continuous function. We note
also that if \( u_0 \in H_0^1 \), then \( E(u(t)) \) is continuous on \([0, +\infty)\). It follows also that \( \frac{du}{dt} \) belongs to \( L^2(\delta, T; L^2(0, 1)) \), for any \( \delta > 0 \). Then Lemma 2.1 in [3, p.189] implies that \( E(u(t)) \) is absolutely continuous on \([\delta, +\infty)\) and
\[
\frac{1}{2} \frac{d}{dt} \left\| \frac{\partial u}{\partial x} \right\|^2 = \left( -\frac{\partial^2 u}{\partial x^2}, \frac{du}{dt} \right), \quad \left( g(t), \frac{du}{dt} \right) = \frac{d}{dt} \psi^2(u(t)),
\]
for a.e. \( t \in [\delta, +\infty) \), where \( g(t) \in \partial \psi^2(u(t)) \).

Then we can take the derivative of \( E(u(t)) \) with respect to \( t \) to obtain
\[
\frac{dE(u(t))}{dt} = \int_0^1 \left( -\frac{\partial^2 u}{\partial x^2} - g(t) \right) \frac{du}{dt} dx = -\int_0^1 \left\| \frac{\partial u}{\partial t} \right\|^2 dx.
\]

The following properties follow:

1. \( E(u(t)) \) is continuous on \((0, +\infty)\);
2. \( E(u(t)) \leq E(u(s)) \), if \( t \geq s > 0 \);
3. If \( E(u(t)) = E(u(0)) \), for some \( t > 0 \), then \( u(\tau) = u(0) \) for any \( \tau \in [0, t] \), i.e. \( u(0) = v \) is a fixed point.

Such a function is called energy or Lyapunov function in the literature. Finally note that, using Young’s and Poincaré inequalities we have that \( E \) is bounded below if (2.6) is satisfied, that is, if \( \omega < \pi^2 \).

We note first that easy computations give
\[
E(0) = 0, \quad E(v_+^n) = E(v_-^n) = -\frac{1}{24n^2}, \quad \text{for } n \geq 1, \text{ if } \omega = 0,
\]
\[
E(0) = 0, \quad E(v_+^n) = E(v_-^n) = \frac{n}{\omega \sqrt{\omega}} \left( \frac{\cos \left( \frac{\sqrt{\omega}}{n} \right) - 1}{\sin \left( \frac{\sqrt{\omega}}{n} \right)} \right) + \frac{1}{2\omega}, \quad \text{if } 0 < \omega < \pi^2.
\]

We note that the function \( n \mapsto \frac{n}{\omega \sqrt{\omega}} \left( \frac{\cos \left( \frac{\sqrt{\omega}}{n} \right) - 1}{\sin \left( \frac{\sqrt{\omega}}{n} \right)} \right) \) is strictly increasing and
\[
\lim_{n \to +\infty} \frac{n}{\omega \sqrt{\omega}} \left( \frac{\cos \left( \frac{\sqrt{\omega}}{n} \right) - 1}{\sin \left( \frac{\sqrt{\omega}}{n} \right)} \right) = -\frac{1}{2\omega}.
\]

Hence,
\[
E(v_+^1) = E(v_-^1) < E(v_+^2) = E(v_-^2) < ... < E(v_+^n) = E(v_-^n) < ... < E(0) = 0 \quad (5.2)
\]
\[
\lim_{n \to +\infty} E(v_+^n) = 0.
\]

For any solution \( u(t) \) we define the omega limit set
\[
\omega (\{u(t)\}) = \{ y : u(t_k) \to y \text{ in } L^2(0, 1), \text{ where } t_k \to +\infty \},
\]
which is non-empty.

**Lemma 5.1** \( \omega (\{u(t)\}) \subset Z \), where \( Z \) is the set of fixed points. Moreover, \( \omega (\{u(t)\}) = z \in Z \), and \( u(t) \to z \), as \( t \to +\infty \), in \( H_0^1(0, 1) \).
Proof. Since \( E \) is non-increasing along the solutions, and bounded below, we deduce that \( E(u(t)) \) converges to some \( I \in \mathbb{R} \) as \( t \to +\infty \).

Also, from the compactness in Corollary 3.2, \( \omega(\{u(t)\}) \) is non empty. Therefore, if \( y \in \omega(\{u(t)\}) \), then there exists a subsequence (again denoted by \( u(t_k) \)) such that \( u(t_k) \to y \) in \( H^1_0 \). The continuity of \( E \) in the space \( H^1_0 \) implies that \( E(y) = l \). Hence, \( E(y) = l \), for all \( y \in \omega(\{u(t)\}) \).

Let us prove that \( y \in Z \). Fix \( t > 0 \). Since \( u(t_k) \to y \) and the multivalued map \( G_0(t,\cdot) \) is upper semicontinuous (see Section 2), we have

\[
\text{dist} \left( G_0(t,u(t_k)), G_0(t,y) \right) \to 0, \text{ as } t_k \to +\infty.
\]

It is known that \( G \in \omega(u(t)) \) is connected. \( \omega(\{u(t)\}) \) is a closed set and it is contained in the global attractor, so that it is compact. If it is not connected, then \( \omega(\{u(t)\}) = \omega_1 \cup \omega_2 \), where \( \omega_i \) are non-empty compact disjoint sets. We take open disjoint sets \( U_i \) such that \( \omega_i \subset U_i \). Since \( u(t) \) is a continuous function, there must exist \( t_j \to +\infty \) such that \( u(t_j) \notin U_1 \cup U_2 \). But the set \( \{u(t_j)\} \) is precompact in \( L^2(0,1) \), and then there exists a subsequence \( u(t_{j_k}) \) converging to some \( z \notin U_1 \cup U_2 \). But \( z \in \omega(\{u(t)\}) \), which is a contradiction.

Finally, we note that the set \( Z \) is countable. Therefore, the only possibility is that \( \omega(\{u(t)\}) \) consists of one point of \( Z \). The point \( z \) attracts \( u(t) \) in \( H^1_0 \), because in other case there would exist a sequence \( u(t_j) \) such that \( \|u(t_j) - z\|_{H^1_0} > \varepsilon \), and then we could obtain a subsequence converging to \( z \) in \( H^1_0 \), a contradiction. \( \blacksquare \)

6 Stability of fixed points

We shall study now the stability of the fixed points in the case \( \omega = 0 \). We say that a fixed point \( v \) of (4.1) is stable in the Banach space \( Y \) if for any \( \rho > 0 \) there exists \( \delta > 0 \) such that if \( \|u_0 - v\|_Y < \delta \), then \( \|u(t) - v\|_Y < \rho \), for any \( t \geq 0 \) and any solution \( u(\cdot) \in \mathcal{D}(u_0) \) (i.e. \( \|y - v\|_Y < \rho \), for any \( t \geq 0 \), \( y \in G_0(t,u_0) \)). In other words, if the initial data is in a sufficiently small neighborhood of the fixed point, then all the solutions remain uniformly in a given neighborhood of the fixed point. In other case we say that it is unstable. We say that the fixed point \( v \) is asymptotically stable if it is stable and there exists \( \delta > 0 \) such that \( \lim_{t \to +\infty} \text{dist} \left( G(t,u_0), v \right) = 0 \), if \( \|u_0 - v\|_Y < \delta \).

We shall prove that the fixed points \( v^+_1, v^-_1 \) are the unique stable equilibria.

We start proving the following result which is independent of the dimension of the problem.

Proposition 6.1 Assume (2.6) and \( f \equiv 0 \). Then (1.1) has a unique positive fixed point that we denote by \( v^+_1 \) and for any nonnegative initial data \( u_0 \) there exists a solution of (1.1) that converges to \( v^+_1 \) as \( t \to +\infty \).

In particular, this implies that the trivial solution \( v_0 = 0 \) is unstable. The same results holds true for negative solutions.

Proof. With the notations of Theorem 3.1 note that positive equilibria must satisfy

\[
\begin{cases}
-\Delta u = \omega u + 1 & \text{in } \Omega \\
u = 0 & \text{on } \Gamma.
\end{cases}
\]
which has a unique solution, since (2.6) is assumed. Let \( U(t) \) be the unique solution to

\[
\begin{aligned}
\frac{\partial U}{\partial t} - \Delta U &= \omega U + 1, \\
U |_{\partial \Omega} &= 0, \\
U(0) &= u_0 \geq 0,
\end{aligned}
\]

which is strictly positive for \( t > 0 \) and it is also a solution of (1.1). Hence, \( U \) can be written as

\( U = z + \phi \), where

\[
\begin{aligned}
\frac{\partial z}{\partial t} - \Delta z &= \omega z, \\
z |_{\partial \Omega} &= 0, \\
z(0) &= u_0 - \phi.
\end{aligned}
\]

Since \( z \) converges to \( 0 \) (again we use that \( \omega < \lambda_1 \)), the result follows. \( \square \)

We return now to problem (3.2).

**Theorem 6.2** (Stability in \( H^1_0(0,1) \)) If \( \omega = 0 \) the fixed points \( v_1^+, v_1^- \) are stable in \( H^1_0(0,1) \).

**Proof.** We take \( v_1^+(x) = -\frac{x^2}{2} + \frac{\rho}{2} \) and put \( v_1 = v_1^+ \). The case \( v_1^- \) is similar. We note that

\[
\frac{d^2}{dx^2} v_1 = -1 \quad \text{and then for any solution of (4.1) with } u_0 \in H^1_0(0,1) \text{ we have that } z(t) = u(t) - v_1 \]

satisfies

\[
\begin{aligned}
\frac{\partial z}{\partial t} - \Delta z &= g(t) - 1, \quad \text{on } (0,1) \times (0, \infty), \\
z(0, t) &= z(1, t) = 0, \\
z(x, 0) &= u_0(x) - v_1(x) \in H^1_0(0,1),
\end{aligned}
\]

where \( g(t) \in H^1_0(u(t)) \), for a.e. \( t \), and \( g \in L^\infty(0, \infty; L^\infty(0,1)) \). It is known that \( z \in C([0,T], H^1_0(0,1)) \), for any \( T > 0 \), [15].

Let \( \|z_0\|_{H^1_0} = \sqrt{\int_0^1 \left| \frac{dz_0}{dx} \right|^2 dx < \frac{\rho}{2}, \rho > 0 \). Let \( t_1 \) be the largest number such that \( \|z(t)\|_{H^1_0} \leq \rho \), for all \( t \leq t_1 \). We shall prove that if \( \rho \) is small enough, then \( t_1 = +\infty \).

Since \( z(x, t) = z(0, t) + \int_0^x \frac{\partial z}{\partial s} ds \) (\( z(\cdot,t) \) is absolutely continuous on \( x \)), we obtain that

\(|z(x, t)| \leq \|z(t)\|_{H^1_0} \leq \rho \), for any \( t \in [0, t_1], x \in [0,1] \). The function \( u(x, t) \) is then positive if \( v_1(x) > \rho \), so that \( g(t, x) - 1 = 0 \). If \( \rho < \frac{1}{8} \), solving \( -\frac{x^2 + x}{2} = \rho \) we can easily compute that \( v_1(x) > \rho \) whenever \( x \in [4\rho, 1 - 4\rho] \).

For \( x \in [0, 4\rho] \) we have

\[
|z(x, t)| \leq \int_0^{4\rho} \left| \frac{\partial z}{\partial s} \right| ds \leq \sqrt{4\rho} \|z(t)\|_{H^1_0} \leq 2\rho^\frac{3}{2},
\]

and the same is valid for \( x \in [1 - 4\rho, 1] \). Again the function \( u(x, t) \) is positive for any \( x \in [0, 4\rho] \) such that \( v_1(x) > 2\rho^\frac{3}{2} \). Now solving \( -\frac{x^2 + x}{2} = 2\rho^\frac{3}{2} \) we obtain that if \( \rho < \frac{1}{16\pi} \), then this is true for \( x \in \left[ 8\rho^\frac{3}{2}, 1 - 8\rho^\frac{3}{2} \right] \). Hence, \( u(x, t) > 0 \), for any \( x \in \left[ 8\rho^\frac{3}{2}, 1 - 8\rho^\frac{3}{2} \right], t \in [0, t_1] \), and \( g(x, t) - 1 = 0 \), for a.e. \( (x, t) \in \left( 8\rho^\frac{3}{2}, 1 - 8\rho^\frac{3}{2} \right) \times (0, t_1) \). We note that \( \rho < \frac{1}{8} \) implies \( 8\rho^\frac{3}{2} < 4\rho \).

Since (6.1) is a particular case of problem (2.4) with \( l(t) = g(t) - 1 \in \partial \psi^2(u(t)) - 1 \), \( \psi^2(u) = \int_0^1 |u| dx \), we can use Proposition 2.2 and Lemma 2.1 in [3, p.189] to have that
\[ \frac{1}{2} \frac{d}{dt} \left\| \frac{\partial z}{\partial x} \right\|^2 = \left( -\frac{\partial^2 z}{\partial x^2}, \frac{dz}{dx} \right) \text{ and } (g(t) - 1, \frac{dv}{dt}) = (g(t), \frac{dv}{dt}) - (1, \frac{dv}{dt}) = \frac{dv}{dt} (u(t) - 1, z(t)). \]

Hence, multiplying (6.1) by \( \frac{dz}{dt} \) we have

\[ \left\| \frac{dz}{dt} \right\|^2 + \frac{1}{2} \frac{d}{dt} \left\| \frac{\partial z}{\partial x} \right\|^2 = \int_0^1 (g(t) - 1) \frac{dz}{dt} dx = \frac{d}{dt} \int_0^1 (|u(t)| - z(t)) dx. \]

Integrating over (0, t) we get

\[ \frac{1}{2} \left\| \frac{\partial z}{\partial x} (t) \right\|^2 \leq \frac{1}{2} \left\| \frac{\partial z}{\partial x} (0) \right\|^2 + \int_0^1 (|u(t)| - z(t) - |u(0)| + z(0)) dx. \]

Since \( |u(x,t)| = u(x,t) = v_1(x) + z(x,t), |u(x,t)| = u(x,0) = v_1(x) + z(x,0) \), for all \( x \in [8\rho^2, 1 - 8\rho^2], t \in [0,t_1] \), we have to consider the last integral only in the intervals \( I_1 = [0, 8\rho^2] \) and \( I_2 = [1 - 8\rho^2, 1] \). But on the other hand, \( |z(x,t)| \leq 2\rho^2 \), and \( |v_1(x)| = v_1(x) \leq 4\rho^2 \) in \( I_1 \cup I_2 \). Hence,

\[ |u(x,t)| = |z(x,t) + v_1(x)| \leq C_1 \rho^2, \text{ for all } x \in I_1 \cup I_2, t \in [0,t_1]. \]

Finally,

\[ \left\| \frac{\partial z}{\partial x} (t) \right\|^2 \leq \left\| \frac{\partial z}{\partial x} (0) \right\|^2 + C_2 \rho^3 \left( \int_0^{8\rho^2} 1 dx + \int_{1 - 8\rho^2}^1 1 dx \right) = \|z_0\|_{H^1_0}^2 + C_3 \rho^3. \]

Choosing \( \rho \leq \frac{1}{4c_3} \), we have

\[ \|z(t)\|^2_{H^1_0} \leq \frac{\rho^2}{4} + \frac{\rho^2}{4} < \rho^2, \text{ for all } t \in [0,t_1]. \]

Since \( t_1 < +\infty \) gives a contradiction, it follows that \( t_1 = +\infty \). \[ \square \]

Now we have:

**Theorem 6.3** *(Stability in \( L^2 (0,1) \)) If \( \omega = 0 \) the fixed points \( v_1^+, v_1^- \) are stable in \( L^2 (0,1) \).*

**Proof.** Put \( v_1 = v_1^+ \). Multiplying (6.1) by \( z \) and using \( |g(x,t) - 1| \leq 2 \) we have

\[ \frac{1}{2} \frac{d}{dt} \|z(t)\|^2 + \|z(t)\|^2_{H^1_0} \leq 2 \int_0^1 |z| dx \leq 2 \|z(t)\|. \] (6.2)

Differentiating we get \( \frac{d}{dt} \|z(t)\| \leq 2 \) and then

\[ \|z(t)\| \leq \|z_0\| + 2t \] (6.3)

\[ \int_0^t \|z(s)\|^2_{H^1_0} ds \leq \frac{1}{2} \|z_0\|^2 + 2 \int_0^t \|z(s)\| \leq \frac{1}{2} \|z_0\|^2 + 2t \|z_0\| + 2t^2. \] (6.4)
Further, we take a sequence $z_0^n \in H_0^1$ converging to $z_0$ in $L^2$. If $z_n(t)$ are the solutions of (6.1) with $z_n(0) = z_0^n$, then Proposition 2.2 gives $z_n \rightarrow z$ in $C([0, T], L^2(0, 1))$ for any $T > 0$. Multiplying (6.1) by $t \frac{dz_n}{dt}$ we have

$$t \left\| \frac{dz_n}{dt} \right\|^2 + \frac{t}{2} \frac{d}{dt} \| z \|^2_{H_0^1} \leq 2t \left\| \frac{dz_n}{dt} \right\|^2 \leq \frac{t}{2} \left\| \frac{dz_n}{dt} \right\|^2 + 2t.$$

Integrating by parts on $(0, T)$ and using (6.4) we obtain

$$\int_0^T \frac{t}{2} \left\| \frac{dz_n}{dt} \right\|^2 dt + \frac{T}{2} \| z_n(T) \|^2_{H_0^1} \leq T^2 + \frac{1}{2} \int_0^T \| z \|^2_{H_0^1} dt \leq 2T^2 + T \| z_0 \| + \frac{1}{4} \| z_0 \|^2.$$

Passing to the limit we have

$$\| z(T) \|^2_{H_0^1} \leq 4T^2 + 2 \| z_0 \| + \frac{1}{2T} \| z_0 \|^2. \quad (6.5)$$

For a given $\rho > 0$ we can choose $\sigma$ and $T$ such that $4T + 2\sigma + \frac{2\rho^2}{T^2} \leq \frac{\rho^2}{4}$, $\sigma + 2T \leq \rho$. Then if $\| z_0 \| \leq \sigma$, (6.3) and (6.5) imply $\| z(t) \| \leq \rho$, for all $t \in [0, T]$, $\| z(T) \|^2_{H_0^1} \leq \frac{\rho^2}{4}$. Finally, choosing $\rho$ small enough Theorem 6.2 gives $\| z(t) \|^2_{H_0^1} \leq \rho$, for all $t \geq T$. Since the first eigenvalue of $-\frac{\partial^2}{\partial x^2}$ in $H_0^1(0, 1)$ is $\lambda_1 = \pi^2$, we have

$$\| z(t) \| \leq \frac{\| z(t) \|^2_{H_0^1}}{\pi} \leq \rho,$$

for any $t \geq T$.

\[ \blacksquare \]

Hence we get:

**Corollary 6.4**  
\( i \) The solution $u(t) = v_1^+$ (respectively $v_1^-$) corresponding to $u_0 = v_1^+$ (respectively $v_1^-$) is unique.  

\( ii \) The equilibrium points $v_1^+$ are asymptotically stable.

**Proof.** The first part is immediate from stability. For the second note that $v_1^\pm$ are stable, isolated, and $\omega(u_0) = z \in Z$, for all $u_0$ (see Lemma 5.1), so that if $\| u_0 - v_1^\pm \| < \delta$, for $\delta$ small enough, then $\omega(u_0) = v_1^\pm$. \[ \blacksquare \]

**Remark 6.5** This stability result is not difficult to prove also in the case $0 < \omega < \pi^2$ with some little changes in the proof.

We shall prove further that the other fixed points are unstable.

**Theorem 6.6** If $\omega = 0$ for any $n \geq 2$ the fixed points $v_n^+$, $v_n^-$ are unstable.

**Proof.** As before we shall consider the case $v_n = v_n^+$. The other case is similar. We define the following approximations of $v_n$:

$$y_n^\alpha(x) = \begin{cases} 
-\frac{x^2}{2} + \frac{1+x}{2n}x, & \text{if } 0 \leq x \leq \frac{1+x}{n}, \\
\frac{1}{2}v_n^+(x) + \frac{x-\omega}{2n^2}, & \text{if } \frac{1+x}{n} \leq x \leq \frac{u-1-x}{n}, \\
\frac{x^2}{2} + \frac{2n-1-x}{2n}x - \frac{u-1}{2n} + \frac{x}{2n}, & \text{if } n \text{ is odd, } \frac{u-1-x}{n} \leq x \leq 1, \\
\end{cases}$$

where $\alpha \in \{0, 1\}$, $\omega \in (0, 2\pi)$, and $\omega = \frac{\pi}{2}$ if $n$ is even.
\[ y_n^\varepsilon(x) = \begin{cases} -\frac{x^2}{2} + \frac{1+\varepsilon}{2\varepsilon}x, & \text{if } 0 \leq x \leq \frac{1+\varepsilon}{n}, \\ \frac{x^2}{2} - \frac{2n-1+\varepsilon}{2n}x + \frac{\varepsilon}{2n}, & \text{if } \frac{1+\varepsilon}{n} \leq x \leq \frac{n-1+\varepsilon}{n}, \\ 0, & \text{if } n \text{ is even}, \\ \frac{x^2}{2} - \frac{2n-1+\varepsilon}{2n}x + \frac{\varepsilon}{2n}, & \text{if } \frac{n-1+\varepsilon}{n} \leq x \leq 1, \end{cases} \]

where \( \varepsilon > 0 \). It is easy to see that \( y_n^\varepsilon \in H_0^1 \) and \( y_n^\varepsilon \to v^+_n \) in \( L^2 \). We can compute that

\[
E(y_n^\varepsilon) = -\frac{1}{24n^2} - \frac{3\varepsilon^2}{4n^3} + \frac{\varepsilon^3}{n^2} - \frac{11\varepsilon^3}{4n^3}, \quad \text{if } n \text{ is odd},
\]

\[
E(y_n^\varepsilon) = -\frac{1}{24n^2} - \frac{3\varepsilon^2}{4n^3} + \frac{\varepsilon^3}{n^2} - \frac{2\varepsilon^3}{3n^3}, \quad \text{if } n \text{ is even},
\]

so that \( E(y_n^\varepsilon) < E(v^+_n) \) for sufficiently small \( \varepsilon \).

Let \( u_\varepsilon(t) \) be a solution with \( u_\varepsilon(0) = y_n^\varepsilon \). Lemma 5.1 implies that \( \omega(\{u_\varepsilon(t)\}) = z \in Z \). Moreover, since \( E(u_\varepsilon(t)) \) is non-increasing, it is clear that \( E(z) = \lim_{t \to +\infty} E(u_\varepsilon(t)) < E(v^+_n) \).

Hence, \( \omega(\{u_\varepsilon(t)\}) \subset \{v^+_1, v^+_1, \ldots, v^+_n-1, v^-_{n-1}\} \). Finally, if we denote

\[
\rho = \min_{n \in \{1, \ldots, n-1\}} \left\{ \|v^+_n - v^+_1\|, \|v^-_n - v^-_{n-1}\| \right\},
\]

then for any \( \sigma > 0 \) there exist \( y_n^\varepsilon \), a solution \( u_\varepsilon(t) \) and \( T > 0 \) such that \( u_\varepsilon(0) = y_n^\varepsilon \), \( \|y_n^\varepsilon - v^+_n\| < \sigma \), and

\[
\|u_\varepsilon(t) - v^+_n\| > \rho, \text{ for all } t \geq T,
\]

so that \( v^+_n \) is unstable. \( \blacksquare \)

Finally, we shall study in further detail the instability of \( v_0 \equiv 0 \).

**Theorem 6.7** If \( \omega = 0 \) for any \( v^+_k \) (respectively \( v^-_k \)) there exists a solution \( u^+_k \) (respectively \( u^-_k \)) with \( u(0) = v_0 = 0 \) such that \( u^+_k(t) \to v^+_k \) (respectively \( u^-_k(t) \to v^-_k \)), as \( t \to +\infty \).

**Remark 6.8** It follows that there exist infinite solutions starting at \( v_0 \) and also that there is a heteroclinic connection from \( v_0 \) to any \( v^+_k \) and \( v^-_k \).

**Proof.** Note that the case \( k = 1 \) is given by Proposition 6.1. Let now \( k = 2 \) and consider the equation

\[
\begin{aligned}
&\frac{\partial u}{\partial t} - \frac{\partial^2 u}{\partial x^2} = 1, \\
&u(0, x) = 0, \\
&u(t, 0) = u(t, 1) = 0.
\end{aligned}
\]

(6.6)

The same arguments than in Proposition 6.1 applied now in the interval \((0, \frac{1}{2})\) proves that the unique solution of (6.6), \( u_1(t) \), converges to \( v^+_2 \) in \( L^2(0, \frac{1}{2}) \). Analogously, replacing \( 1 \) by \(-1 \) in (6.6) and working in the interval to \((\frac{1}{2}, 1)\), we prove that the unique solution, \( u_2(t) \), converges to \( v^+_2 \) in \( L^2(\frac{1}{2}, 1) \). We put \( u(t, x) = u_1(t, x), \) if \( x \in [0, \frac{1}{2}] \), \( u(t, x) = u_2(t, x), \) if \( x \in [\frac{1}{2}, 1] \). It is clear that \( u(t) \to v^+_2 \) in \( L^2(0, 1) \). We have to prove that \( u(t) \) is a strong solution for any \( T > 0 \). First we check that \( u(\cdot) \in C([0, T], L^2(0, 1)) \) is absolutely continuous in any compact subset \([a, b] \subset (0, T)\). Since \( \|u(t) - u(s)\|^2 = \int_0^1 (u_1(t, x) - u_1(s, x))^2 \, dx + \int_{\frac{1}{2}}^1 (u_2(t, x) - u_2(s, x))^2 \, dx \) and \( u_1(t), u_2(t) \) are absolutely continuous in \([a, b]\) with respect to the spaces \( L^2(0, \frac{1}{2}) \) and \( L^2(\frac{1}{2}, 1) \), respectively, the result follows. Hence, \( u(t) \) is a.e. differentiable in \((0, T)\) and it remains to check that \( u(t) \in H^2(0, 1) \) and satisfies (2.2) for a.e. \( t \in (0, T) \) with \( g(t, x) = 1 \), if
where $\lambda$ is a particular case of (3.2). It follows from these conditions that $H$

Let us consider now a parameterized family of functions $H_\varepsilon \in C^2(\mathbb{R})$, $\varepsilon > 0$, such that

$$
H_\varepsilon (0) = 0, \quad H_\varepsilon' (0) = \frac{1}{\varepsilon},
$$

$$
H_\varepsilon' (s) > 0, -1 < H_\varepsilon (s) < 1, \forall s,
$$

$$
H_\varepsilon'' (s) < 0, \quad \text{if } s > 0, \quad H_\varepsilon'' (s) > 0, \quad \text{if } s < 0,
$$

$$
\lim_{s \to +\infty} H_\varepsilon (s) = 1, \quad \lim_{s \to -\infty} H_\varepsilon (s) = -1.
$$

Moreover, we shall assume that $H_\varepsilon$ is odd and

$$
H_\varepsilon (s) > g_\varepsilon (s), \quad \text{if } s > 0, \quad H_\varepsilon (s) < g_\varepsilon (s), \quad \text{if } s < 0,
$$

where

$$
g_\varepsilon (s) = \begin{cases} 
1 - \varepsilon, & \text{if } s \geq \varepsilon, \\
\frac{1 - \varepsilon}{\varepsilon} s, & \text{if } -\varepsilon \leq s \leq \varepsilon, \\
-1 + \varepsilon, & \text{if } s \leq -\varepsilon.
\end{cases}
$$

It follows from these conditions that

$$
\text{dist} (\text{Graph}(H_\varepsilon), \text{Graph}(H)) \leq \varepsilon.
$$

The maps $H_\varepsilon$ are approximations of the map $H_0 (s)$ as $\varepsilon \to 0$. It is clear from (7.3) and (7.2) that if $s_n \to s > 0$ (respectively $< 0$), $\varepsilon_n \to 0$, then $H_{\varepsilon_n} (s_n) \to H_0 (s) = 1$ (respectively $-1$). We study the Chafee-Infante like problem

$$
\begin{cases}
\frac{\partial u}{\partial t} - \frac{\partial^2 u}{\partial x^2} = H_\varepsilon (u) = \lambda_\varepsilon f_\varepsilon (u), & \text{in } (0,1) \times (0, T), \\
u (0, t) = u (1, t) = 0, \\
u (x, 0) = u_0 (x),
\end{cases}
$$

(7.4)

where $\lambda_\varepsilon = \frac{1}{\varepsilon}$, $f_\varepsilon (u) = \frac{1}{\varepsilon} H_\varepsilon (u)$. This equation is an approximation of (4.1) with $\omega = 0$ which is a particular case of (3.2).

It is well known that if $n^2 \pi^2 < \lambda_\varepsilon \leq (n + 1)^2 \pi^2$, $n \in \mathbb{N}$, then equation (7.4) has exactly $2n + 1$ equilibria denoted by $v_{\varepsilon k}^+, v_{\varepsilon k}^-$, $k = 1, \ldots, n$, with the following properties [7, p.121]:

1. $\frac{d}{dx} v_{\varepsilon k}^+ (0) > 0$, $\frac{d}{dx} v_{\varepsilon k}^- (0) < 0$;
2. \( v_{xk}^+, v_{xk}^- \) vanish \( k - 1 \) times in \( 0 < x < 1 \).

Furthermore, if \( n^2 \pi^2 < \lambda_k < (n + 1)^2 \pi^2 \) then all equilibria are hyperbolic.

The construction of the fixed points \([7, p.121]\) and the fact that \( H_x \) is odd gives us that the points in \((0, 1)\) where \( v_{xk}^+, v_{xk}^- \) vanish are \( a_j = \frac{j}{k}, j = 1, \ldots, k - 1 \), which coincide with the same points for \( v_k^+ \), see (4.6) and Remark 4.3. The functions \( v_{xk}^+ \) (respectively \( v_{xk}^- \)) are positive (respectively negative) in \( \frac{2j}{k} < x < \frac{2j+1}{k} \), and negative (respectively positive) in \( \frac{2j+1}{k} < x < \frac{2j+2}{k} \), \( j = 0, \ldots, \left[ \frac{k-1}{2} \right] \), where \([\cdot]\) denotes the integer part of a number. Moreover, \( v_{xk}^+ = -v_{xk}^- \).

Now consider a sequence \( \varepsilon_n \to 0 \), where \( n^2 \varepsilon_n^2 < \lambda_{\varepsilon_n} < (n_{\varepsilon_n} + 1)^2 \pi^2 \), with \( n_{\varepsilon_n} \to \infty \).

**Lemma 7.1** Let \( k \) be fixed. Then \( v_{\varepsilon nk}^+ \) (respectively \( v_{\varepsilon nk}^- \)) cannot converge to \( 0 \) in \( H^1_0(0, 1) \) as \( \varepsilon_n \to 0 \).

**Proof.** Consider the interval \([0, \frac{1}{k}]\). Suppose that \( v_{\varepsilon nk}^+ \to 0 \) in \( H^1_0(0, 1) \). Then \( v_{\varepsilon nk}^+ \to 0 \) in \( C([0, 1]) \).

The function \( v_{\varepsilon nk}^+ \) has a unique maximum in that interval at some \( a \in (0, \frac{1}{k}) \) and \( \frac{d}{dx} v_{\varepsilon nk}^+ (a) = 0 \) (in fact \( a = \frac{1}{2k} \), but this is not important for our proof). Let \( x_0(\varepsilon_n) \) be the first point where \( v_{\varepsilon nk}^+ (x_0) = \varepsilon_n \) or \( x_0(\varepsilon_n) = a \) if such a point does not exist.

We state that \( x_0(\varepsilon_n) \to 0 \), as \( \varepsilon_n \to 0 \). It is clear from (7.1) that the second derivative of \( v_{\varepsilon nk}^+ \) is negative in \((0, \frac{1}{k})\), and then \( v_{\varepsilon nk}^- (x_0(\varepsilon_n)) x \leq v_{\varepsilon nk}^+ (x) \leq \varepsilon_n \), for all \( x \in [0, x_0] \). Hence, integrating first on \((s, a)\) and then on \((0, x)\) with \( x \leq x_0 \), and using (7.2), we have

\[
\begin{align*}
\frac{d}{dx} v_{\varepsilon nk}^+ (s) &= \int_s^a H_{\varepsilon n} \left( v_{\varepsilon nk}^+ (\tau) \right) d\tau \\
v_{\varepsilon nk}^+ (x) &= \int_0^x \int_0^a H_{\varepsilon n} \left( v_{\varepsilon nk}^+ (\tau) \right) d\tau ds + \int_0^x \int_s^{x_0} H_{\varepsilon n} \left( v_{\varepsilon nk}^+ (\tau) \right) d\tau ds \\
&\geq \int_0^x \int_s^{x_0} \frac{1 - \varepsilon_n}{\varepsilon_n} v_{\varepsilon nk}^+ (\tau) d\tau ds \\
&\quad \geq \frac{v_{\varepsilon nk}^+ (x_0)}{x_0(\varepsilon_n)} \frac{1 - \varepsilon_n}{\varepsilon_n} \int_0^x \int_s^{x_0} \tau d\tau ds.
\end{align*}
\]

Hence

\[
1 \geq \frac{1 - \varepsilon_n}{\varepsilon_n} \left( \frac{x_0 x}{2} - \frac{x^3}{x_0 6} \right).
\]

It follows that \( x_0(\varepsilon_n) \to 0 \), as \( \varepsilon_n \to 0 \).

Let \( \delta > 0 \) be such that \( x_0(\varepsilon_n) \leq \delta \). We note also that \( v_{\varepsilon nk}^+ (x) \geq \varepsilon_n \), for all \( x \in [x_0, a] \).

Therefore, integrating (7.5) over \((\delta, x)\) with \( x > \delta \) we have

\[
v_{\varepsilon nk}^+ (x) \geq v_{\varepsilon nk}^+ (\delta) + \int_\delta^x \int_s^a (1 - \varepsilon_n) d\tau ds
\]

and passing to the limit we obtain a contradiction if \( v_{\varepsilon nk}^+ \to 0 \) in \( C([0,1]) \). For the sequence \( v_{\varepsilon nk}^- \) the proof is similar. The lemma is proved. \( \blacksquare \)

We are now ready to prove the following:

**Lemma 7.2** \( v_{\varepsilon nk}^+ \) (respectively \( v_{\varepsilon nk}^- \)) converges to \( v_k^+ \) (respectively \( v_k^- \)) in \( H^1_0(0, 1) \) as \( \varepsilon_n \to 0 \).
Proof. Note that Corollary 3.2 applied to (7.4) implies that \( v^+_{\varepsilon_{nk}} \) is bounded in, say, \( H^1_0 \). Moreover, it is easy to see that they are bounded in \( H^2 \). Hence, we may assume that \( v^+_{\varepsilon_{nk}} \) converges to some \( v \) weakly in \( H^2 \), strongly in \( H^1_0 \) and in \( C^1([0,1]) \).

We have to check that \( v \) is a fixed point. It is clear that the functions \( g_{\varepsilon_{nk}} = H_{\varepsilon_{nk}}(v^+_{\varepsilon_{nk}}) \) are bounded in \( L^\infty(0,1) \). Passing to a subsequence we can then assume that \( g_{\varepsilon_{nk}} \) converges to some \( g \) weakly in \( L^2(0,1) \). It is clear that \( -\partial^2_v v = g \) and the result will follow if we prove the inclusion \( g(x) \in H_0(v(x)) \) for a.e. \( x \in (0,1) \). By Masur’s theorem [21] there exist \( z_m \in V_m = \text{conv} \left( \bigcup_{k \geq m} g_{\varepsilon_{ik}} \right) \) such that \( z_m \rightarrow g \), as \( m \rightarrow \infty \), strongly in \( L^2(0,1) \). Taking a subsequence we have \( z_m(x) \rightarrow g(x) \), a.e. in \( (0,1) \). Since \( z_m \in V_m \), we get \( z_m = \sum_{i=1}^{N_m} \lambda_i g_{\varepsilon_{ik}} \), where \( \lambda_i \in [0,1] \), \( \sum_{i=1}^{N_m} \lambda_i = 1 \) and \( k_i \geq m \), \( \forall i \). Now (7.3) implies that

\[
\text{dist}(g_{\varepsilon_{ik}}(x), H_0(v(x))) \rightarrow 0, \text{ as } k \rightarrow \infty, \text{ for a.e. } x.
\]

Indeed, if \( v(x) = 0 \), then \( g_{\varepsilon_{ik}}(x) \in [-1,1] = H_0(v(x)) \). If \( v(x) > 0 \), then

\[
\text{dist}(g_{\varepsilon_{ik}}(x), H_0(v(x))) = |H_{\varepsilon_{ik}}(v_{\varepsilon_{ik}}(x)) - 1| \rightarrow 0, \text{ as } k \rightarrow \infty.
\]

The argument is similar if \( v(x) < 0 \). Hence, for any \( \delta > 0 \) and a.e. \( x \) there exists \( m(x,\delta) \) such that

\[
g_{\varepsilon_{ik}}(x) \subset [a(x) - \delta, b(x) + \delta], \quad \forall k \geq m,
\]

where \( [a(x), b(x)] = H_0(v(x)) \). Hence, \( z_m(x) \subset [a(x) - \delta, b(x) + \delta] \), as well. Passing to the limit we obtain

\[
g(x) \in [a(x), b(x)], \quad \text{a.e. on } (0,1).
\]

We shall prove further that \( v = v^+_{k} \). We know that \( v^+_{\varepsilon_{nk}}(x) > 0 \), for all \( x \in (0, \frac{1}{2}) \), and the convergence in the space \( C([0,1]) \) implies that \( v(x) \geq 0 \) in \( [0, \frac{1}{2}] \) and \( v(0) = v\left(\frac{1}{2}\right) = 0 \). By (4.6) the only possibilities are \( v = v^+_{k} \) or \( v \equiv 0 \). Lemma 7.1 gives us that \( v = v^+_{k} \).

For the sequence \( v_{\varepsilon_{nk}} \) the proof is similar. \( \blacksquare \)

Corollary 7.3 \( v^+_{\varepsilon_{ik}} \) (respectively \( v^-_{\varepsilon_{ik}} \)) converges to \( v^+_{k} \) (respectively \( v^-_{k} \)) in \( H^1_0(0,1) \) as \( \varepsilon \rightarrow 0^+ \).

8 Heteroclinic connections between fixed points

Let us consider now the important question about which heteroclinic connections can exist between the fixed points in the case \( \omega = 0 \). These connections give us some information about the structure of the global attractor.

Recall first that a complete trajectory is a function \( u(t) \) defined on \( (-\infty, \infty) \) such that \( u(\cdot) \) is a strong solution of (4.1) on any interval \( (-T,T) \). This implies that \( u(t) \in G_0(t - \tau, u(\tau)) \), for all \( t \geq \tau \). Since the global attractor is invariant, it is easy to see that it is equal to the union of all complete bounded trajectories. Indeed, if \( u_0 \in \mathcal{A} \), then we take an arbitrary solution \( u_1(t) \), \( t \geq 0 \), with \( u_1(0) = u_0 \) and some points \( u_i \in \mathcal{A}, i = -1, -2, \ldots \), such that \( u_i \in G_0(1, u_{i+1}) \). Then there exist solutions \( u_i(t) \) defined on \( [i, i+1] \) such that \( u_i(i) = u_i \) and \( u_i(i+1) = u_{i+1} \). Concatenating all these solutions we obtain a complete bounded trajectory lying on the global attractor. Hence, any \( y \in \mathcal{A} \) belongs to a complete bounded trajectory.
Conversely, if \( u(t) \) is a complete bounded trajectory, then it is clear that \( B = \bigcup_{t \in (-\infty, +\infty)} u(t) \) satisfies \( B \subset G_0(t, B) \) and

\[
\text{dist} (G_0(t, B), A) \to 0, \text{ as } t \to +\infty.
\]

Therefore, \( B \subset A \). The same results are valid for the attractors \( A_\epsilon \) defined in Section 3.

We have defined before the \( \omega \)-limit set. For a complete trajectory we define as usual the \( \alpha \)-limit set by

\[
\alpha \left(\{ u(t) \}\right) = \{ y : u(t_k) \to y \text{ in } L^2(0,1), \text{ where } t_k \to -\infty \},
\]

which is non-empty.

**Lemma 8.1** Let \( u(t) \) be a bounded complete trajectory. Then \( \alpha \left(\{ u(t) \}\right) \subset Z \), where \( Z \) is the set of fixed points. Moreover, \( \alpha \left(\{ u(t) \}\right) = z \in Z \), and \( u(t) \to z \), as \( t \to -\infty \), in \( H^1_0(0,1) \).

**Proof.** We note that the global attractor \( \mathcal{A} \) is precompact in \( H^1_0 \) by Corollary 3.2 and then \( B = \bigcup_{t \in (-\infty, +\infty)} u(t) \) is precompact in \( H^1_0 \). The rest of the proof is the same as in Lemma 5.1 but taking the subsequences \( t_k \) converging to \( -\infty \).

We have obtained in Lemmas 5.1 and 8.1 that every complete bounded trajectory satisfies

\[
u(t) \xrightarrow{t \to +\infty} z_2 \in Z
\]

\[
u(t) \xrightarrow{t \to -\infty} z_1 \in Z.
\]

In such a case we say that there exists a heteroclinic connection from \( z_1 \) to \( z_2 \). In the sequel we shall denote this property by \( z_1 \rightsquigarrow z_2 \). Note that the compactness in Corollary 3.2 implies that although we are now considering the convergence in the phase space \( L^2(0,1) \) to the fixed point, we also have convergence in stronger norms, e.g. in \( H^1_0 \).

We note further that the global attractors consists of the fixed points and all the heteroclinic connections between them. Hence, if we know all the possible connections we have a complete description of the structure of the global attractor.

We shall consider further the family of approximations given in (7.4). We have seen that if \( n^2 \pi^2 < \lambda_\epsilon < (n + 1)^2 \pi^2 \), then this equation has exactly \( 2n + 1 \) hyperbolic fixed points denoted by \( v_\epsilon 0 \equiv 0, v^+_{\epsilon k}, v^-_{\epsilon k}, k = 1, ..., n \), and it is well known [8] that

\[
v_\epsilon 0 \rightsquigarrow v^+_{\epsilon k}, \quad v_\epsilon 0 \rightsquigarrow v^-_{\epsilon k},
\]

\[
v^+_{\epsilon k} \rightsquigarrow v^+_{\epsilon i}, \quad v^+_{\epsilon k} \rightsquigarrow v^-_{\epsilon i},
\]

\[
v^-_{\epsilon k} \rightsquigarrow v^+_{\epsilon i}, \quad v^-_{\epsilon k} \rightsquigarrow v^-_{\epsilon i},
\]

whenever \( k > i \geq 1 \), that is, there exists at least one heteroclinic connection from 0 to any other fixed point and from any \( v^+_{\epsilon k} \) to any \( v^-_{\epsilon k} \) if \( k > i \geq 1 \). Moreover, these are all the possible connections; no more bounded complete trajectories can exist. We note again that the complete trajectory \( u_\epsilon (t) \) converges to the fixed point in the space \( H^1_0(0,1) \).

Using these known connections between fixed points in the approximations we shall prove some connections in the limit problem. Note that we have already shown in Theorem 6.7 that for any \( k \geq 1 \),

\[
v_\epsilon 0 \rightsquigarrow v^+_k.
\]
For the rest of the results, the Lyapunov function defined by (5.1) will play a crucial role in the proofs. We recall first that the inequalities (5.2) hold. Since the Lyapunov function \( E \) is not increasing with respect to \( t \) in every trajectory \( u(t) \) it follows that any connection from \( v_k^+ \) to \( v_i^+ \) with \( i \geq k \geq 1 \) is forbidden. Then the question becomes if it is true that for \( 1 \leq i < k \) there exists at least one heteroclinic connection from \( v_k^+ \) to \( v_i^+ \) as it occurs in the approximations. In this direction note that in view of (7.4), and since we assume the closure is understood in the space \( H \), where \( y \) to some solution \( \cdot \in D \), \( T > 0 \) (see Corollary 3.6), implies that \( u_{\varepsilon_j} (\tau_j - t_j) \rightarrow y(0) = v \), so that \( v^* = v \).

If \(|t_j - \tau_j| \neq 0\), then passing to a subsequence we can assume that for some \( \delta > 0 \) we have

\[ \delta + t_j < \tau_j, \text{ for all } j. \]

Let us define the set

\[ L_{(t_j, \tau_j)} = \cap_{\varepsilon > 0} \cup_{\varepsilon < \varepsilon} \cup_{t_j \leq \tau_j \leq t_j} u_{\varepsilon_j}(t)^{-1} H^1_0, \]

where the closure is understood in the space \( H^1_0 \). In the approximation problem (7.4) we have also the Lyapunov function (see [7, p.119]):

\[ E_{\varepsilon}(u) = \int_0^1 \left( \frac{1}{2} \left| \frac{\partial}{\partial x} u(x) \right|^2 dx - \int_0^u H_{\varepsilon}(s) ds \right) dx. \]
It is easy to check that $E_{\varepsilon}(y_{\varepsilon}) \to E(y)$, if $y_{\varepsilon} \to y$ in $H^{1}_{0}$ as $\varepsilon \to 0$. For this, note that

$$\int_{0}^{y(x)} H_{\varepsilon}(s) \, ds \to |y(x)|,$$

for all $x \in [0, 1]$. Indeed, $y_{\varepsilon} \to y$ in $C([0, 1])$ and then we have three cases. If $y(x) = 0$, then

$$\left| \int_{0}^{y_{\varepsilon}(x)} H_{\varepsilon}(s) \, ds - y(x) \right| \leq \left| \int_{0}^{\varepsilon} H_{\varepsilon}(s) \, ds \right| + \left| \int_{\varepsilon}^{y_{\varepsilon}(x)} H_{\varepsilon}(s) \, ds - y(x) \right|.$$

It follows from (7.2) that $H_{\varepsilon}(s) = 1 - f_{\varepsilon}(s)$, for $s \geq \varepsilon$, where $0 < f_{\varepsilon}(s) < \varepsilon$. Hence,

$$\left| \int_{0}^{y_{\varepsilon}(x)} H_{\varepsilon}(s) \, ds - y(x) \right| \leq \varepsilon + \left| y_{\varepsilon}(x) - \varepsilon - y(x) \right| + \varepsilon (y_{\varepsilon}(x) - \varepsilon) \to 0.$$

For $y(x) < 0$ the proof is similar. On the other hand, $\left| \int_{0}^{y_{\varepsilon}(x)} H_{\varepsilon}(s) \, ds \right| \leq |y_{\varepsilon}(x)| \leq C$, for all $x$. Thus Lebesgue's theorem implies $\int_{0}^{y_{\varepsilon}(x)} H_{\varepsilon}(s) \, ds \to |y|$ in $L^{1}(0, 1)$, and then $E_{\varepsilon}(y_{\varepsilon}) \to E(y)$.

It follows then that $E_{\varepsilon}(u_{\varepsilon}(t)) \to E(v)$, $E_{\varepsilon}(u_{\varepsilon}(\tau)) \to E(v^*)$. Since $E_{\varepsilon}(u_{\varepsilon}(\tau)) \leq E_{\varepsilon}(u_{\varepsilon}(t)) \leq E_{\varepsilon}(u_{\varepsilon}(t_{j}))$, for all $t \in [0, \tau - t_{j}]$, we have that $E(v^*) \leq E(y) \leq E(v)$, for any $y \in \Lambda(t_{j}, \tau_{j})$.

Suppose that $v \neq v^*$ and $E(v) = E(v^*)$. Then

$$E(y) = E(v) = E(v^*),$$

and there exists $y \in \Lambda(t_{j}, \tau_{j})$ different from $v$ and $v^*$. Indeed, we take two open sets $U_{1}, U_{2}$ (in $H^{1}_{0}$) such that

$$v \in U_{1}, \quad v^* \in U_{2}, \quad U_{1} \cap U_{2} = \emptyset.$$

Since $u_{\varepsilon}(t_{j}) \in U_{1}$, $u_{\varepsilon}(\tau) \in U_{2}$, for $j \geq J$, and $u_{\varepsilon}(t)$ is continuous, there must exist $s_{j} \in (t_{j}, \tau_{j})$ such that $u_{\varepsilon}(s_{j}) \notin U_{1} \cup U_{2}$. Passing to a subsequence by Corollary 3.2 we obtain

$$u_{\varepsilon}(s_{j}) \to y \in \Lambda(t_{j}, \tau_{j}),$$

where $y \notin U_{1} \cup U_{2}$, $y \neq v$, $y \neq v^*$ (the limit is understood in the space $H^{1}_{0}$). Moreover, $y$ cannot be a fixed point, because there are only two with the same value of the Lyapunov function, see (5.2).

Further, it is clear arguing as before that $s_{j} + \xi < \tau_{j}$, for some $\xi > 0$ and any $j$. The functions $u_{\varepsilon}(t) = u_{\varepsilon}(s_{j} + t)$ converge by Corollary 3.6 to some solution $w(\cdot) \in D(y) \in C([0, \xi], H^{1}_{0})$. It is evident that $w(t) \in \Lambda(t_{j}, \tau_{j})$, for any $t \in [0, \xi]$, so that $E(w(t)) = E(v) = E(v^*)$. This contradicts that $y$ is not a fixed point and this contradiction proves the Lemma. ■

**Corollary 8.3** Let now

$$\Lambda = \cap_{\varepsilon>0} \cup_{\varepsilon<\varepsilon_{0}} \cup_{-\infty \leq t \leq \infty} u_{\varepsilon}(t)^{H^{1}_{0}}.$$

If $y \in \Lambda$ is a fixed point such that $y \neq v_{k}$, $y \neq v_{l}$, then $E(v_{i}) < E(y) < E(v_{k})$. The number of fixed points in $\Lambda$ is finite if $v_{k} \neq v_{0}$.

**Proof.** In a similar way as in the proof of Lemma 8.2 we can check that $E(v_{i}) \leq E(y) \leq E(v_{k})$, for all $y \in \Lambda$. If $u_{\varepsilon}(t_{j}) \to y \neq v_{k}$ is a fixed point, then choosing a sequence $u_{\varepsilon}(\tau_{j}) \to v_{k}$, $\tau_{j} > t_{j}$, and using Lemma 8.2 we obtain that $E(y) < E(v_{k})$. The same argument is valid for $v_{l}$. The last statement is evident. ■

Now we are ready to prove the existence of a finite chain of complete bounded trajectories from $v_{k}$ to $v_{l}$ if $k > i \geq 1$.
Lemma 8.4 Let \( \omega = 0 \) and let \( v_1 \) and \( v_2 \) be two fixed points different from \( v_0 = 0 \) such that \( E(v_1) > E(v_2) \) \( \text{(i.e.,} \ v_1 = v_k, \ v_2 = v_i, \ k > i \geq 1) \). Then there exist a finite number of fixed points \( y_{-r}, ..., y_{-1}, y_0, y_1, ..., y_m \) such that

\[
E(v_1) > E(y_{-r}) > \cdots > E(y_0) > \cdots > E(y_m) > E(v_2),
\]

\[
v_1 \sim y_{-r} \sim \cdots \sim y_0 \sim y_1 \sim \cdots \sim y_m \sim v_2.
\]

**Proof.** We choose the sequences \( v_{1\varepsilon_j} = v_{\varepsilon_j}, v_{2\varepsilon_j} = v_{\varepsilon_j} \). From Lemma 7.2 it follows that

\[
v_{1\varepsilon_j} \to v_1, \quad v_{2\varepsilon_j} \to v_2, \quad \text{as} \ \varepsilon_j \to 0, \quad \text{in} \ H_0^1.
\]

Let \( u_{\varepsilon_j}(t) \) be a complete trajectory of (7.4) such that \( u_{\varepsilon_j}(t) \to v_{1\varepsilon_j}, \ u_{\varepsilon_j}(t) \to v_{2\varepsilon_j}. \)

Fix \( T > 0 \). Using Corollary 3.2 we obtain that up to a subsequence \( u_{\varepsilon_j}(-T) \to y \) in \( H_0^1 \). Corollary 3.6 implies then that \( u_{\varepsilon_j} \) converges in \( C([-T, T], H_0^1) \) to some solution \( u \) of (4.1) with \( u(-T) = y \). We choose successive subsequences for \(-2T, -3T...\) and by the standard diagonal procedure we obtain that a subsequence \( u_{\varepsilon_j} \) converges to a complete trajectory \( u \) of (4.1) in \( C([-T, T], H_0^1) \) for any \( T > 0 \). We note also that the solution \( u(t) \) is a bounded complete trajectory contained in the global attractor \( A_0 \). Indeed, \( u_{\varepsilon_j}(t) \in A_{\varepsilon_j} \) and by Theorem 3.5, dist \((A_{\varepsilon_j}, A_0) \to 0, \) so that \( u(t) \in A_0 \) for all \( t \). Lemmas 5.1, 8.1 imply the existence of two fixed points \( y_0, y_1 \) such that \( u(t) \to y_0, u(t) \to y_1 \).

Suppose that \( y_0 \neq v_1 \).

It is clear that we can choose a subsequence \( u_{\varepsilon_j}(\tau_j) \) converging to \( y_0 \) as \( j \to \infty \). We take \( \delta > 0 \) small enough, so that in the closed ball \( B_\delta(y_0) \) of radius \( \delta \) (in the space \( H_0^1 \)) there is no any other fixed point, and, moreover, the value of the Lyapunov function \( E(y) \) of any point \( y \in B_\delta(y_0) \) is different from the value of \( E \) of any other fixed point (excluding, of course, the pair of \( y_0, y_1 \)) and there exists \( \xi > 0 \) such that

\[
E(w) < E(y_0) - \xi \leq E(y) \leq E(y_0) + \xi < E(v_1), \quad \text{for all} \ y \in B_\delta(y_0),
\]

where \( w \) (respectively \( v_1 \)) is the first fixed point in the scale (5.2) such that \( E(w) < E(y_0) \) (respectively \( E(v_1) > E(y_0) \)).

On the other hand, since \( u_{\varepsilon_j}(t) \to v_{1\varepsilon_j} \) and \( v_{1\varepsilon_j} \notin B_\delta(y_0) \) (note that \( v_{1\varepsilon_j} \to v_1 \neq y_0 \) in \( H_0^1 \)), there exist \( t_j < \tau_j \) such that

\[
\|u_{\varepsilon_j}(t_j) - y_0\|_{H_0^1} = \delta,
\]

\[
\|u_{\varepsilon_j}(t) - y_0\|_{H_0^1} > \delta, \quad \text{for all} \ t < t_j.
\]

Define \( w_{\varepsilon_j}(t) = u_{\varepsilon_j}(t_j + t) \). Passing to a subsequence we obtain as before that \( w_{\varepsilon_j} \) converges to some bounded complete trajectory \( w \) in \( C([-T, T], H_0^1) \), for all \( T > 0 \), and \( w_{\varepsilon_j}(t_j) \to w(0) = w_0, \ \|w_0 - y_0\|_{H_0^1} = \delta. \)

We shall prove that \( w(t) \to y_0 \). Let first \( \tau_j - t_j \to +\infty \). Arguing as in Lemma 8.2 we obtain that for any \( z \in \Lambda(t, \tau_j) = \bigcap_{\varepsilon > 0} \bigcup_{\varepsilon \leq \varepsilon < \varepsilon, \ v_{1\varepsilon_j} \leq t \leq \tau_j} u_{\varepsilon_j}(t) \) the inequality

\[
E(y_0) - \xi \leq E(z) \leq E(y_0) + \xi
\]

holds. Since \( w(t) \in \Lambda(t, \tau_j) \), for any \( t \in \mathbb{R} \), we have that the fixed point \( \bar{z} = \lim_{t \to +\infty} w(t) \) satisfies the same inequality. Hence, either \( \bar{z} = y_0 \) or \( \bar{z} \) is the pair of \( y_0 \) with the same value of
Theorem 8.5
If the Lyapunov function. Again passing to a subsequence we can choose \( t_j \leq s_j \leq \tau_j \) such that \( u_{\varepsilon_j} (s_j) \to \overline{z} \) in \( H^1_0 \). Hence, Lemma 8.2 implies that \( \overline{z} = y_0 \).

Let now \(|\tau_j - t_j|\) be bounded by a constant \( K \). Passing to a subsequence \( \tau_j - t_j \to s \geq 0 \) and then \( u_{\varepsilon_j} (\tau_j) = w (\tau_j - t_j) \to w (s) \). Therefore, \( w (s) = y_0 \).

Lemma 8.1 gives \( w (t) \to_{t \to -\infty} y_1 \in \mathbb{Z} \), with \( E (y_{-1}) > E (y_0) \). We note also that \( w (t) \to_{t \to +\infty} y_0 \). In the second case (with \(|\tau_j - t_j|\) bounded) we can put \( w (t) = y_0 \), for all \( t \geq s \). We have obtained an heteroclinic connection from \( y_{-1} \) to \( y_0 \), i.e. \( y_{-1} \rightsquigarrow y_0 \).

If \( y_{-1} \neq v_1 \), repeating the same argument we obtain \( y_{-2} \in \mathbb{Z} \) with \( E (y_{-2}) > E (y_1) \) such that \( y_{-2} \rightsquigarrow y_{-1} \). Continuing in this way we obtain \( y_{-3}, y_{-4}, \) etc. By Corollary 8.3, \( E (v_1) \leq E (y_{-1}) \leq E (v_2) \) and \( E (v_1) = E (y_{-1}) \) if and only if \( v_1 = y_{-1} \). Since the sequence \( a_i = E (y_{-1}) \) is strictly increasing and the number of possible fixed points is finite, there must exist \( r \) such that \( y_{-r-1} = v_1 \). Hence, we have obtained the chain of connections

\[
y_1 \rightsquigarrow y_{-r} \rightsquigarrow y_{-(r-1)} \rightsquigarrow \cdots \rightsquigarrow y_{-1} \rightsquigarrow y_0 \rightsquigarrow y_1.
\]

In a similar way we obtain the chain of connections from \( y_1 \) to \( v_2 \). \( \blacksquare \)

As a consequence of Lemma 8.4 we obtain the following:

**Theorem 8.5** If \( \omega = 0 \) for any \( n \geq 2 \) the following heteroclinic connections exist:

\[
\begin{align*}
v^+_n & \rightsquigarrow v^+_{n-1}, & v^+_n & \rightsquigarrow v^-_{n-1}, \\
v^-_n & \rightsquigarrow v^+_n, & v^-_n & \rightsquigarrow v^-_{n-1}.
\end{align*}
\]

We shall prove further the following connection:

**Theorem 8.6** If \( \omega = 0 \), then \( v^+_k \rightsquigarrow v^+_k \), for all \( k > 1 \).

**Proof.** It is clear from the formulas of the fixed points that

\[
\begin{align*}
v^-_1 (x) & \leq v^+_k (x) \leq v^+_1 (x), \\
v^-_1 (x) & \leq v^-_k (x) \leq v^-_1 (x),
\end{align*}
\]

for all \( x \in [0, 1] \) and \( k > 1 \), and also that there is not any other \( v_i \) such that \( v_k (x) \leq v_i (x) \) or \( v_i (x) \leq v_k (x) \) for all \( x \). The same holds for (7.4).

Take, for example, \( v_k = v^+_k \), \( v_1 = v^+_1 \). The other cases are similar. Take the fixed points of the approximations \( v^+_1 \) and \( v^+_1 \). It is well known (see [7]) that the eigenfunction corresponding to the first eigenvalue of the linearization of (7.4) around \( v^+_1 \) is positive. Also note that from (8.1), this equilibrium is hyperbolic.

We claim now that in the unstable manifold of \( v^+_1 \) there exists \( u^0_1 \) such that \( u^0_1 (x) \geq v^+_1 (x) \) for all \( x \in (0, 1) \).

Once this is shown we have then that the corresponding solution \( u_{\varepsilon_j} (t) = u_{\varepsilon_j} (t, u^0_1) \) satisfies \( u_{\varepsilon_j} (x, t) \geq v^+_1 (x) \), for all \( x \) and \( t \), by monotonicity, and \( u_{\varepsilon_j} (t) \to_{t \to +\infty} v^+_1 \). Since \( u_{\varepsilon_j} (x, t) \geq v^+_1 (x) \) the only possibility is that \( u_{\varepsilon_j} (t) \to_{t \to +\infty} v^+_1 \). Hence \( u_{\varepsilon_j} (t) \) is a suitable complete trajectory that realizes the connection \( v^+_1 \rightsquigarrow v^+_1 \).

Now, we know from Lemma 8.4 that

\[
v^+_k \rightsquigarrow y_{-r} \rightsquigarrow \cdots \rightsquigarrow y_m \rightsquigarrow v^+_1,
\]
for some fixed points $y_i$. In the proof of that lemma it is shown that there exists a subsequence $u_{x_j}(\tau_j)$ converging to $y_i$ in $H^1_0(0,1)$ (and then in $C([0,1])$). Hence, $v^+_k(x) \leq y_i(x)$, for all $x$, so that either $y_i = v^+_k$ or $y_i = v^+_1$. It follows then that $v^+_k \sim v^+_1$.

We now prove the claim above. Note that from Corollary 3.2, the local analysis around the hyperbolic equilibria $v^+_{\epsilon,j,k}$ can be set within a $W^{1,p}$ setting and the local invariant theorem in [7] applies. Denote by $\phi^{1}_{\epsilon,k}$ the first eigenfunction of the linearization around $v^+_{\epsilon,j,k}$. Then for $\mu \geq 0$ the point $v^+_{\epsilon,j,k} + \mu \phi^{1}_{\epsilon,k}$ lies in the linear unstable manifold of $v^+_{\epsilon,j,k}$. Since the unstable manifold is tangent to the linear unstable manifold at $v^+_{\epsilon,j,k}$, for sufficiently small $\mu > 0$, there exists $u^0_{\epsilon,j} \in W^{1,2}_{\text{loc}}(v^+_{\epsilon,j,k})$ such that $\|u^0_{\epsilon,j} - (v^+_{\epsilon,j,k} + \mu \phi^{1}_{\epsilon,k})\|_{W^{2-s,p}} = o(\mu)$, for any $\delta > 0$. In particular the above is true in the $C^1$ topology. Since $v^+_{\epsilon,j,k} + \mu \phi^{1}_{\epsilon,k}$ is strictly above $v^+_{\epsilon,j,k}$ in $(0,1)$ and is a $C^1$ function, the claim is proved.

Finally, we shall obtain some more connections in the case $\omega = 0$ using a self-similarity property of the solutions. In fact note that we obtained in Remark 4.2 that for $\omega = 0$ the equilibria are self-similar. The same property is valid for any solution of the parabolic problem $u(t)$. In fact, if we define $u_n(t) = \frac{1}{n^2} u(n^2 t, n x)$, for $x \in [0, \frac{1}{n^2}]$, $u_n(t) = -\frac{1}{n^2} \frac{1}{2^2} u\left(n^2 t, n \left(x - \frac{1}{n}\right)\right)$, for $x \in \left[\frac{1}{n^2}, \frac{2}{n^2}\right]$, and so on, then we obtain a new solution. This can be verified by a direct substitution on $u_n$ in (4.1) with $\omega = 0$. Hence, if $u(t)$ is a complete trajectory going from $v_1$ to $v_k$, $k > i \geq 1$, then $u_n(t)$ is a complete trajectory going from $v_{nk}$ to $v_{ni}$.

We have proved the following results, which somehow extends Theorem 6.7:

**Theorem 8.7** Let $\omega = 0$. If $v_k \sim v_i$, $k > i \geq 1$, then $v_{nk} \sim v_{ni}$, for all $n \in \mathbb{N}$.

This result allow us to obtain new heteroclinic connections from Theorems 8.5 and 8.6. For example, from $v_2 \sim v_1$ it follows $v_4 \sim v_2$, $v_6 \sim v_3$, etc.
