Abstract

A general scheme for determining and studying integrable deformations of algebraic curves is presented. The method is illustrated with the analysis of the hyperelliptic case. An associated multi-Hamiltonian hierarchy of systems of hydrodynamic type is characterized.

Key words: Hydrodynamic Systems. Algebraic curves

1 Introduction

Algebraic curves arise in the study of various problems for nonlinear differential equations. The theory of finite-gap solutions of integrable equations and the Whitham averaging theory are, probably, the most known examples of the relevance of algebraic curves and their deformations in the context of nonlinear integrable models (see e.g. [1]-[3]).

In this work we deal with a class of integrable deformations of algebraic curves \( C \) defined by polynomial equations \[ F(p, k) := p^N - \sum_{n=0}^{N-1} u_n(k)p^n = 0, \quad u_n \in \mathbb{C}[k]. \] (1)

We investigate deformations \( C(x, t) \) consistent with the degrees of the polynomials \( u_n \) and such that there exists an action function \( S = S(k, x, t) \) verifying

1. The multiple-valued function \( p = p(k) \) determined by (1) can be expressed as 
   \[ p = S_x. \]

2. The function \( S_t \) represents, like \( p = S_x \), a meromorphic function on \( C(x, t) \) with poles only at \( k = \infty \).

As a consequence of these conditions \( p \) obeys an equation of the form

\[ \partial_t p = \partial_x Q, \] (2)

where \( Q := S_t \) is assumed to be of the form

\[ Q = \sum_{r=0}^{N-1} a_r(k)p^r, \quad a_r \in \mathbb{C}[k]. \]

This type of deformations arises in a natural way within the quasiclassical (dispersionless) limit of integrable systems [5]-[14]. For example, the Gel’fand-Dikii hierarchies are associated with the spectral problems

\[ \left( \partial_x^N - \sum_{n=1}^{N-2} u_n(x) \partial_x^n \right) \psi - k^N \psi = 0, \] (3)
and their quasiclassical limit is determined by the leading order of the expansion arising from inserting the ansatz

$$\psi = \exp \left( \frac{S}{\epsilon} \right), \quad \epsilon \to 0,$$

and substituting $\partial_x \to \epsilon \partial_x$ in (2). Thus, $p := S_x$ satisfies

$$p^N - \sum_{n=0}^{N-1} u_n(x)p^n - k^N = 0,$$

and the Gel-fand-Dikii equations for the coefficients $u_n$ become a hierarchy of systems of hydrodynamic type.

These deformations of algebraic curves are present not only in the theory of reductions of the dispersionless KP (dKP) hierarchy but also in more general contexts as the universal Whitham hierarchy [10], the hierarchies of rational Lax equations [11]-[12] or the quasiclassical limits of integrable systems associated with energy-dependent Schrödinger spectral problems [13]-[14].

In this paper we follow the suggestions of [13] and propose a general scheme for analyzing and classifying these deformations without relying on any particular type of dispersionless hierarchy. We take equations (1)-(2) as our starting point and express the coefficients $u_n$ of (1) as elementary symmetric functions of the branches $p_i$ of $p$ (Viète theorem) to formulate the corresponding system of evolution equations for $u_n$. They turn out to admit a simple general form in terms of symmetric functions of $p_i$ involving the so-called power sums functions. The requirement of consistency with the polynomial character of the coefficients $u_n$ as functions of $k$ imposes severe constraints to the curve (1). To deal with the problem of characterizing consistent deformations we develop a technique based on solving Lenard type relations, which can be viewed as a quasiclassical version of the fruitful resolvent method [15] of the theory of Lax pairs. Thus, we provide a class of consistent deformations determined by systems of hydrodynamic type for the coefficients $u_n$. Moreover, they have a natural associated set of Riemann invariants. The analysis of the completeness of these sets of Riemann invariants is found to be related to the existence of gauge symmetries.

To illustrate our analysis we study in detail the hyperelliptic case

$$p^2 - v(k)p - u(k) = 0, \quad u, v \in \mathbb{C}[k].$$
We present a class of quasiclassical deformations of these curves determined by a hierarchy of compatible multi-Hamiltonian systems of hydrodynamic type which is analyzed from the $R$-matrix point of view. A quantum (dispersionful) counterpart of this hierarchy is also discussed. The analysis of the deformations of both the general case of (1) and its reductions will be presented elsewhere.

## 2 Algebraic curves

We start with some notation conventions to enunciate the results of algebraic geometry \[16-22\] which are particularly helpful in our analysis.

Let $C$ denote an algebraic curve determined by (1). Its associated function $p = p(k)$ describes a multiple-valued function determined by $N$ branches $p_i = p_i(k) \ (i = 0, \ldots, N - 1)$ satisfying

$$F(p, k) = \prod_{i=0}^{N-1} (p - p_i(k)).$$

(4)

We denote by $\mathbb{C}((k))$ the field of power series in $k$ with at most a finite number of terms with positive powers

$$\sum_{n=-\infty}^{N} a_n k^n, \quad N \in \mathbb{Z}.$$  

The following general result \[16-17\] will be used in our subsequent analysis:

**Theorem 1. (Newton Theorem)**

There exists a positive integer $l$ such that the $N$ branches

$$p_i(z) := \left. p_i(k) \right|_{k=z^l},$$

(5)

are elements of $\mathbb{C}((z))$. In other words, they are Laurent series of finite order as $z \to \infty$

$$p_i(z) = \sum_{n=0}^{N_i} a_n^{(i)} z^n + \sum_{n=1}^{\infty} b_n^{(i)} z^{-n}, \quad i = 1, \ldots, N.$$  

Furthermore, if $F(p, k)$ is irreducible as a polynomial over the field $\mathbb{C}((k))$ then $l_0 = N$ is the least permissible $l$ and the branches $p_i(z)$ can be labeled so that

$$p_i(z) = p_0(\epsilon^i z), \quad \epsilon := \exp \frac{2\pi i}{N}.$$  

4
Notation convention Henceforth, given an algebraic curve $C$ we will denote by $z$ the variable associated with the least positive integer $l_0$ for which the substitution $k = z^{l_0}$ implies $p_i \in \mathbb{C}((z)), \forall i$.

Examples

The curves

$$p^2 - u(k) = 0, \quad u(k) := \sum_{i=0}^{m} u_i k^i, \quad u_m \neq 0,$$

have the branches

$$p_\pm := \sqrt{u(k)} = \sqrt{u_m k^m \left(1 + O\left(\frac{1}{k}\right)\right)}, \quad k \to \infty,$$

so that $F := p^2 - u(k)$ is an irreducible (reducible) polynomial over $\mathbb{C}((k))$ for odd (even) $m$ and

$$k = z, \quad \text{for even } m, \quad k = z^2, \quad \text{for odd } m.$$

According to Viète theorem [19] we may write the coefficients $u_n$ of (1) in terms of the branches $p_i$ as

$$u_n = (-1)^{N-n-1} s_{N-n}, \quad (6)$$

where $s_k = s_k(p_0, \ldots, p_{N-1})$ are the elementary symmetric polynomials

$$s_k = \sum_{0 \leq i_1 < i_2 < \cdots < i_k \leq N-1} p_{i_1} \cdots p_{i_k}.$$

In our study we will use also the so-called power sums [19]

$$P_k = p_0^k + \cdots + p_{N-1}^k, \quad k \geq 0.$$

These symmetric functions are polynomials in the elementary symmetric functions $s_k$ and, consequently, they can be written as polynomials in the coefficients $u_n$. In order to obtain these polynomials, one can use Newton recurrence formulas [19]

$$P_k = k u_{N-k} + u_{N-k+1} P_1 + \cdots + u_{N-1} P_{k-1}, \quad 1 \leq k \leq N,$$

$$P_k = u_0 P_{k-N} + u_1 P_{k-N+1} + \cdots + u_{N-1} P_{k-1}, \quad k > N,$$

(7)
as well as the explicit determinant expressions \[21\]

\[
P_k = \begin{vmatrix}
  u_{N-1} & 1 & 0 & \ldots & 0 \\
  -2u_{N-2} & u_{N-1} & 1 & \ldots & 0 \\
  \vdots & \vdots & \ddots & \ddots & \ddots \\
  (-1)^{k}(k-1)u_{N-k+1} & \cdots & 1 \\
  (-1)^{k+1}k u_{N-k} & \cdots & u_{N-1}
\end{vmatrix}, \tag{8}
\]

where it is assumed that \(u_N := -1, \ u_n := 0, \ n > N\). One has also a similar determinant formula for \(u_n\) in terms of \(P_k\)

\[
u_n = -\frac{(-1)^{N-n}}{(N-n)!} \begin{vmatrix}
  \mathcal{P}_1 & 1 & 0 & \ldots & 0 \\
  \mathcal{P}_2 & \mathcal{P}_1 & 2 & \ldots & 0 \\
  \vdots & \vdots & \ddots & \ddots & \ddots \\
  \mathcal{P}_{N-n} & \cdots & \mathcal{P}_1 & N-n-2 \\
  \mathcal{P}_{N-n} & \cdots & \cdots & \mathcal{P}_1
\end{vmatrix}, \tag{9}
\]

where \(0 \leq n \leq N - 1\).

3 Quasiclassical deformations of algebraic curves

Let us consider the problem of characterizing families \(C(x,t) \ (x,t \in \mathbb{C})\) of algebraic curves

\[
F := p^N - \sum_{n=0}^{N-1} u_n(k,x,t)p^n = 0, \quad u_n \in \mathbb{C}[k]. \tag{10}
\]

which admit a multiple-valued function \(S = S(k,x,t) \ (\text{action function})\) verifying

\[
p = S_x.
\]

Furthermore, we assume that

\[
Q := S_t,
\]

is, like \(p\), a meromorphic function on \(C(x,t)\) which has poles at \(k = \infty\) only. Thus we assume that \(Q\) can be expressed in the form

\[
Q = \sum_{r=0}^{N-1} a_r(k)p^r, \quad a_r \in \mathbb{C}[k]. \tag{11}
\]
The coefficients \(a_r\), and consequently the function \(Q\), will be explicitly dependent on \(x\) and \(t\) also.

Thus the deformations of (10) satisfying these requirements are characterized by equations of the form

\[
\partial_t p = \partial_x \left( \sum_{r=0}^{N-1} a_r(k) p^r \right), \quad a_r \in \mathbb{C}[k].
\] (12)

We will refer to the flows of the form (12) as quasiclassical deformations of the curve (10). They are directly connected to Lax equations of quasiclassical type. To see this property notice that in terms of the branches of \(p\), the flow (12) reduces to the system

\[
\partial_t p_i = \partial_x Q_i, \quad i = 0, \ldots, N - 1
\] (13)

\[
Q_i : = \sum_{r=0}^{N-1} a_r(k) p^r_i.
\]

These equations imply the existence of \(N\) branches \(S_i = S_i(z, \cdot, \cdot) \in \mathbb{C}(z)\) of \(S\) verifying

\[
\frac{dS_i}{dp_i} dx + dQ_i dt + m_i dz, \quad m_i := \frac{\partial S_i}{\partial z},
\]

where \(k = z^{k_0}\). Hence we have

\[
d p_i \wedge dx + dQ \wedge dt = dz_i \wedge dm_i,
\] (14)

where \(z_i = z(p_i, x, t), \quad i = 0, \ldots, N - 1\) stand for the functions obtained by inverting \(p_i = p_i(z, x, t)\) \((i = 0, \ldots, N - 1)\). We now consider the change of variables

\[(p_i, x, t) \mapsto (z_i, x, t),\]

and use the standard technique of [6]. Thus by identifying the coefficients of \(dp_i \wedge dx, \ dp_i \wedge dt\) and \(dx \wedge dt\) in (14), we find

\[
\begin{align*}
\frac{\partial z_i}{\partial p_i} \frac{\partial m_i}{\partial x} &= 1, \\
\frac{\partial z_i}{\partial p_i} \frac{\partial m_i}{\partial t} &= \frac{\partial Q_i}{\partial p_i}, \\
\frac{\partial z_i}{\partial x} \frac{\partial m_i}{\partial t} &= \frac{\partial Q_i}{\partial dx},
\end{align*}
\]
so that the functions $z_i$ satisfy the quasiclassical Lax equations

$$\frac{\partial z_i}{\partial t} = \frac{\partial Q_i}{\partial p_i} \frac{\partial z_i}{\partial x} - \frac{\partial Q_i}{\partial x} \frac{\partial z_i}{\partial p_i}, \quad i = 0, \ldots, N - 1. \quad (15)$$

Our next step is to characterize the evolution law of the coefficients $u_n$ induced by (12). From (13) it follows

$$\frac{\partial u_n}{\partial t} = \sum_{i,j} \frac{\partial u_n}{\partial p_i} \partial_x (a_j p^i_j).$$

At this point it is important to use the following identities

$$\frac{\partial u_n}{\partial p_i} = p_i^{N-n-1} - \sum_{m=n+1}^{N-1} u_m p_i^{m-n-1}, \quad (16)$$

which derive from (1) by differentiating with respect to $p_i$ and identifying coefficients of powers of $p$ in the resulting equation

$$\frac{F}{p - p_i} = \sum_n \frac{\partial u_n}{\partial p_i} p^n.$$ 

Thus, one deduces at once that in terms of the variables $u_n$ the flow (12) reduces to the system

$$\partial_t u = J_0 a, \quad (17)$$

where we are denoting

$$u := \begin{pmatrix} u_{N-1} \\ \vdots \\ u_0 \end{pmatrix}, \quad a := \begin{pmatrix} a_0 \\ \vdots \\ a_{N-1} \end{pmatrix},$$

and $J_0$ is the matrix differential operator

$$J_0 := T^T V^\top \partial_x V, \quad (18)$$

where

$$T := \begin{pmatrix} 1 & -u_{N-1} & \cdots & -u_1 \\ 0 & 1 & \cdots & -u_2 \\ \cdots & \cdots & \cdots & \cdots \\ 0 & \cdots & 1 \end{pmatrix}, \quad (19)$$
and $V$ is the Vandermonde matrix

$$V := \begin{pmatrix}
1 & p_{N-1} & \cdots & p_{N-1}^N \\
& \cdots & \cdots & \cdots \\
& \cdots & \cdots & \cdots \\
1 & p_0 & \cdots & p_0^{N-1}
\end{pmatrix}. \tag{20}
$$

The explicit expression of the operator $J_0$ in terms of the coefficients $u_n$ follows from the observation that the matrix elements of $V^\top \partial_x V$ can be written as

$$\left(V^\top \partial_x V\right)_{ij} = \mathcal{P}_{i+j} \partial_x^j + \frac{j}{i+j} \mathcal{P}_{i+j,x}, \quad 0 \leq i, j \leq N-1, \tag{21}$$

where $\mathcal{P}_k(p_0, \ldots, p_{N-1})$ are the power sums of the variables $p_i$. Hence, the system (17) becomes ($u_N := -1$)

$$\partial_t u_n = - \sum_{r=0}^{N-n-1} \sum_{m=0}^{N-1} u_{n+r+1} \left( \mathcal{P}_{m+r} \partial_x + \frac{m}{m+r} \mathcal{P}_{m+r,x} \right) a_m. \tag{22}$$

**Example 1**

For $N = 2$, the equation for the curve is

$$F := p^2 - u_1 p - u_0 = 0, \tag{23}$$

and the first power sums are

$$\mathcal{P}_1 = u_1, \quad \mathcal{P}_2 = u_1^2 + 2 u_0.$$ 

Thus we find

$$J_0 = \begin{pmatrix}
2 \partial_x & \partial_x (u_1) \\
-u_1 \partial_x & 2 u_0 \partial_x + u_0, x
\end{pmatrix}. \tag{24}$$

**Example 2**

For $N = 3$

$$F := p^3 - u_2 p^2 - u_1 p - u_0 = 0, \tag{25}$$

and

$$\mathcal{P}_1 = u_2, \quad \mathcal{P}_2 = 2 u_1 + u_2^2,$$

$$\mathcal{P}_3 = 3 u_0 + 3 u_1 u_2 + u_2^3,$$

$$\mathcal{P}_4 = 4 u_0 u_2 + 2 u_1^2 + 4 u_1 u_2^2 + u_2^4,$$
\[
J_0 = \begin{pmatrix}
3\partial_x & u_2\partial_x + u_{2,x} & (2u_1 + u_2^2)\partial_x + (2u_1 + u_2^2)x \\
-2u_2\partial_x & 2u_1\partial_x + u_{1,x} & (3u_0 + u_1u_2)\partial_x + 2u_{0,x} + 2u_1u_{2,x} \\
-u_1\partial_x & 3u_0\partial_x + u_{0,x} & u_0u_2\partial_x + 2u_0u_{2,x}
\end{pmatrix}
\]  \tag{26}

### 3.1 Consistency conditions and Lenard relations

Our main aim is to determine expressions for \( \mathbf{a} \) depending on \( z \) and \( \mathbf{u} \) such that (22) is consistent with the polynomial dependence of \( \mathbf{u} \) on the variable \( k \). That is to say, if \( d_n := \text{degree}(u_n) \) are the degrees of the coefficients \( u_n \) as polynomials in \( k \), then (22) must satisfy

\[
\text{degree}(J_0\mathbf{a})_n \leq d_n, \quad \forall n.
\]

In case of consistency (22) will provide a system of hydrodynamic type for the coefficients of the polynomials \( u_n \) and, as a consequence of (13), the coefficients of the expansions of the branches

\[
p_i(z) = \sum_{n=0}^{N_i} h_n^{(i)}(\mathbf{u}) z^n + \sum_{n=1}^{\infty} \frac{h_n^{(i)}(\mathbf{u})}{z^n}, \quad i = 1, \ldots, N, \quad k = z^l,
\]

are conserved densities.

Our main strategy for finding consistent systems is based on using Lenard type relations

\[
J_0\mathbf{R} = 0, \quad \mathbf{R} := (R_1, \ldots, R_N)^\top, \quad R_i \in \mathbb{C}(k),
\]  \tag{27}

and then considering systems of the form

\[
\mathbf{u}_t = J_0\mathbf{a}, \quad \mathbf{a} := \mathbf{R}_+.
\]  \tag{28}

Here \((\cdot)_+\) and \((\cdot)_-\) indicate the parts of non-negative and negative powers in \( k \), respectively. In these cases from the identity

\[
J_0\mathbf{a} = J_0\mathbf{R}_+ = -J_0\mathbf{R}_-,
\]

it is clear that a sufficient condition for the consistency of (28) is that

\[
\text{degree}(J_0)^{nm} \leq d_n + 1,
\]  \tag{29}
for all $n$ and all $m$ such that $a_m = (R_+)_m \neq 0$.

If we impose (29) for all $0 \leq n, m \leq N - 1$, we get a sufficient condition for consistency which only depends on the curve (11) and does not refer to the particular solution of the Lenard relation involved in (28).

Examples

From (24) it is straightforward to see that for $N = 2$ the systems of the form (28) verifying (29) for all $0 \leq n, m \leq 1$ are characterized by the constraint

$$d_1 \leq d_2 + 1.$$  \hspace{1cm} (30)

For $N = 3$ if we impose (29) for all $0 \leq n, m \leq 2$ then from (26) we get the constraints

$$d_2 \leq 1, \quad d_1 \leq d_2 + 1, \quad d_2 \leq d_1 + 1,$$

$$d_0 \leq d_1 + 1, \quad d_1 \leq d_0 + 1,$$  \hspace{1cm} (31)

which lead to the following thirteen nontrivial choices for $(d_0, d_1, d_2)$

$$(1, 0, 0), (0, 1, 0), (1, 1, 0), (2, 1, 0),$$

$$(0, 0, 1), (1, 0, 1), (0, 1, 1), (1, 1, 1)$$

$$(2, 1, 1), (0, 2, 1), (1, 2, 1), (2, 2, 1),$$

$$(3, 2, 1).$$

Examples of flows (28) in which some components of $a$ vanish identically arise by imposing reduction conditions to the curve (11). For instance, let us consider the curve (13)

$$p^N - u_0(k) = 0, \quad u_0 \in \mathbb{C}[k].$$

The branches of $p$ are

$$p_i(k) = \epsilon^i p_0(k), \quad p_0(k) := N^{1/N}u_0(k), \quad \epsilon := \exp \left( \frac{2\pi i}{N} \right),$$  \hspace{1cm} (32)

with $N^{1/N}u_0(k)$ being a given $N$-th root of $u_0(k)$. The systems (13) which are compatible with (32) are those of the form

$$\partial_t p_i = \partial_x (a_1(k)p_i),$$

$$(13)$$
so that the corresponding evolution law for $u_0$ is
\[ \partial_t u_0 = J_0 a_1, \quad J_0 := N p_0^{N-1} \partial_x (p_0) = N u_0 \partial_x + u_{0,x}. \]

Thus, if $d$ denotes the degree of $u_0(k)$, we get the following solutions of the Lenard relation $J_0 R = 0$ in $\mathbb{C}((k))$

\[ R_M = \frac{k^{M+\frac{d}{N}}}{p_0(k)} = \frac{k^{M+\frac{d}{N}}}{\sqrt{u_0(k)}}, \quad M \geq 0. \]

They determine the following infinite set of consistent systems for any degree $d$ of $u_0(k)$

\[ \partial_{t_M} u_0 = (N u_0 \partial_x + u_{0,x}) \left( \frac{k^{M+\frac{d}{N}}}{\sqrt{u_0(k)}} \right). \]

Let us consider now the general case of (1). There is a natural class of solutions of the Lenard relations (27). Indeed, from the expression (18) of $J_0$ it is obvious that for any constant vector $c \in \mathbb{C}^N$

\[ R := V^{-1} c, \]

is a solution of (27). Furthermore, according to (16)

\[ V T = \left( \frac{\partial (u_{N-1}, \ldots, u_0)}{\partial (p_{N-1}, \ldots, p_0)} \right)^\top, \]

so that

\[ V^{-1} = T \left( \frac{\partial (p_{N-1}, \ldots, p_0)}{\partial (u_{N-1}, \ldots, u_0)} \right)^\top. \]

In this way, we have a set of basic solutions $R_i = V^{-1} c_i$, $(c_i)_j := \delta_{ij}$ of the Lenard relations given by

\[ R_i := T \left( \frac{\partial p_i}{\partial u_{N-1}} \ldots \frac{\partial p_i}{\partial u_0} \right)^\top, \quad i = 0, \ldots, N - 1. \]

We notice that direct implicit differentiation of (11) gives

\[ \frac{\partial p_i}{\partial u_j} = \frac{p_i^j}{F_p(p_i)}. \]
In summary, systems of the form

$$\partial_t u = J_0 \left( T \nabla C \right)^+_\pi,$$

where

$$C = \oint \frac{dz}{2\pi i} \int dx \sum_i f_i(z) p_i, \quad f_i \in \mathbb{C}[z],$$

$$\nabla C = \left( \frac{\delta C}{\delta u_{N-1}} \cdots \frac{\delta C}{\delta u_0} \right)^\top,$$

with $\gamma$ being the unit circle in $\mathbb{C}$, are consistent provided the following conditions are satisfied

$$\text{degree} \left( J_0 \right)_{nm} \leq d_n + 1,$$  \hspace{1cm} (37)

$$\frac{\delta C}{\delta u_n} \in \mathbb{C}(\langle z \rangle^l),$$  \hspace{1cm} (38)

for all $0 \leq n, m \leq N - 1$.

### 3.2 Gelfand-Dikii flows

Let us show how the systems (36) include the quasiclassical versions of the Gelfand-Dikii hierarchies [6]. To this end we consider curves (11) of the form

$$F := p^N - \sum_{n=1}^{N-1} u_n(x,t) p^n - v_0(x) - z^N = 0.$$

They give rise to a matrix $T$ which is $z$-independent, so that the corresponding systems (36) become

$$\partial_t u = J \left( \nabla C \right)^+_\pi,$$  \hspace{1cm} (39)
where $J := J(z, u)$ is the symplectic operator
\[
J := T^T V^T \partial_x VT
\]
\[
= \left( \frac{\partial (u_{N-1}, \ldots, u_0)}{\partial (p_{N-1}, \ldots, p_0)} \right) \partial_x \left( \frac{\partial (u_{N-1}, \ldots, u_0)}{\partial (p_{N-1}, \ldots, p_0)} \right)^T ,
\] (40)
\[
J_{ij} = \sum_{l=0}^{i} \sum_{m=0}^{j} u_{N+l-i} \left( p_{l+m} \partial_x + \frac{m}{l+m} p_{l+m,x} \right) u_{N+m-j} ,
\] (41)
where we are denoting $u_N := -1$.

From (7) one proves at once that for $N \leq i \leq 2N - 1$ the functions $p_i$ are linear in $z^N$
\[
p_i = z^N p_{1,i} + p_{2,i},
\]
and
\[
T \left( \begin{array}{c} p_{1,2N-1} \\ \vdots \\ p_{1,N} \end{array} \right) = \left( \begin{array}{c} p_{N-1} \\ \vdots \\ p_0 \end{array} \right)
\]
Hence, as a consequence it follows that $J$ is of the form
\[
J(z, u) = z^N J_1 + J_2.
\]
In particular the operator $J_1$ is given by ($u_N := -1$)
\[
(J_1)_{ij} = \begin{cases} 
- \left( (2N - i - j) u_{2N-i-j} \partial_x + (N - j) u_{2N-i-j,x} \right) & \text{if } i + j \geq N \\
0 & \text{otherwise}
\end{cases}
\]
The operators $J_1$ and $J_2$ form a pair of compatible symplectic operators which describe the quasiclassical limits of the Gelfand-Dikii symplectic operators for the standard hierarchies of scalar Lax pairs [15].

Let us denote by $p_0$ the branch of $p$ such that
\[
p_0 = z + \frac{h_0(u)}{z} + \frac{h_n(u)}{z^n} + \ldots , \quad z \to \infty.
\] (43)
The $N$-th dispersionless Gelfand-Dikii hierarchy can be formulated as the system of flows

$$\frac{\partial z}{\partial t_M} = \frac{\partial Q_M}{\partial p_0} \frac{\partial z_i}{\partial x} - \frac{\partial Q_M}{\partial x} \frac{\partial z}{\partial p_0}, \quad M \geq 1,$$

(44)

where $z := z(p_0, x, t)$ and

$$Q_M(p_0, x, t) := \left(z^M\right)_{\oplus}, \quad t = (t_1, \ldots, t_n, \ldots).$$

Here $(\cdot)_{\oplus}$ and $(\cdot)_{\ominus}$ denote the parts of non-negative and negative powers in $p_0$, respectively. It is straightforward to deduce that the Gelfand-Dikii hierarchy (44) corresponds to the system of flows

$$\partial_t u = J\left(\nabla C_M\right)_+,$$

(45)

where the functionals $C_M$ are given by

$$C_M[u] := \oint_\gamma \frac{dz}{2\pi i} \int d\gamma \sum_j (\epsilon^j z)^M p_0(\epsilon^j z).$$

Alternatively, due to the Lenard relation

$$J\left(\nabla C_M\right)_+ = -J\left(\nabla C_M\right)_-, $$

we have

$$\partial_t u = NJ_2\left(\nabla h_M\right) = -NJ_1\left(\nabla h_{M+N}\right).$$

(46)

3.3 Riemann invariants and gauge transformations

From (15) it follows that the values $z_{i,s} := z_i(p_s, u)$ corresponding to points $p_{i,s}$ at which

$$\frac{\partial z_i}{\partial p}(p_{i,s}, u) = 0,$$

are Riemann invariants of the hydrodynamic system (22). Therefore an important question is to know under what conditions these Riemann invariants are sufficient to integrate (22). It turns out that this problem is closely related to the analysis of the quasiclassical version of gauge transformations of integrable systems (20).
By a gauge transformation of a consistent system (12) we mean a map \( \mathbf{p} \rightarrow \mathbf{p} + g, \ g = g(z, x, t) \)

\[ p_i \rightarrow p_i + g, \quad g \in \mathbb{C}[z], \ \forall i, \]

such that the induced transformation on the coefficients \( u_n \)

\[ u_n \rightarrow \sum_{r=0}^{N-n} \binom{n + r}{r} u_{n+r} g^r, \]

preserves the degrees \( d_n \) of \( u_n \) as polynomials in \( z \).

Gauge transformations possess an obvious set of \( N - 1 \) independent invariants

\[ w_i := p_i - p_{i+1}, \quad i = 0, \ldots, N - 2, \]

and a gauge variable

\[ \rho := \frac{1}{N} u_{N-1} = \frac{1}{N} \sum_i p_i, \quad \rho \rightarrow \rho + g. \]

Like in the dispersionful case [20], we may describe the dynamical variables \( u_n \) in terms of \( N - 1 \) gauge invariants and the gauge variable \( \rho \).

As far as the Riemann invariants \( z_{is} = z_{is}(u) \) are concerned we observe that they satisfy

\[ R(z_{is}) = 0, \]

where \( R(z) \) is the discriminant of \( F \) (the resultant of the function \( F \) and its derivative \( F_p \) with respect to \( p \)). It is given by [22]

\[ R(z) = (-1)^{N(N-1)/2} \prod_{i>j} (p_i(z) - p_j(z))^2, \]

which is obviously a gauge invariant. Hence we conclude that the Riemann invariants \( z_{is} = z_{is}(u) \) are gauge invariants. Therefore, they cannot describe degrees of freedom associated with gauge variables.

4 Deformations of Hyperelliptic curves

The hyperelliptic curves are characterized by quadratic equations in \( p \)

\[ F := p^2 - v(k, x)p - u(k, x) = 0, \quad (47) \]
where
\[ \begin{align*}
v &= \sum_{i=0}^{d_1} v_i k^i, \quad u = \sum_{i=0}^{d_0} u_i k^i.
\end{align*} \]

The branches of \( \mathbf{p} \) are given by
\[ p\pm = \frac{1}{2} \left( v \pm \sqrt{v^2 + 4u} \right), \quad (48) \]
and the map \((p_+, p_-) \mapsto (v, u)\) is
\[ v = p_+ + p_-, \quad u = -p_+ p_. \quad (49) \]
Let us denote
\[ d := \max(2d_1, d_0). \]

Notice that \( F \) is irreducible (reducible) over \( \mathbb{C}((k)) \) for \( d \) odd (even). Thus we set
\[ k = z, \text{ for } d \text{ even}; \quad k = z^2, \text{ for } d \text{ odd}. \quad (50) \]
According to (36) we consider equations of the form
\[ \partial_t \mathbf{u} = J_0 \left( T \nabla C \right)_+, \quad (51) \]
where
\[ \mathbf{u} := \begin{pmatrix} v \\ u \end{pmatrix}, \quad J_0(v, u) = \begin{pmatrix} 2\partial_x & \partial_x (v) \\ -v\partial_x & 2u\partial_x + u_x \end{pmatrix}, \quad T = \begin{pmatrix} 1 & -v \\ 0 & 1 \end{pmatrix}, \]
for functionals
\[ C = \oint_{\gamma} \frac{dz}{2\pi i} \int dx \left( f_+(z) p_+ + f_-(z) p_- \right), \]
As we have seen above these systems are consistent provided
\[ d_1 \leq d_0 + 1, \]
and
\[ \nabla C \in \mathbb{C}((z^2)), \text{ if } d \text{ is odd.} \]
By direct calculation it is straightforward to check that
\[ T(\nabla C^{(\pm)}) = \pm \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \nabla C^{(\pm)}, \quad C^{(\pm)} := \oint \frac{dz}{2\pi i} \int d\gamma \, p_\pm \]

Hence, without loss of generality, we can generate the set of flows (51) from the hierarchy
\[ \partial_{t_N} \mathbf{u} = J \left( \nabla C_N \right)_+, \quad N \geq 0, \]
where \( J = J(u, v) \) is the operator
\[ J := \begin{pmatrix} -2\partial_x & \partial_x(v) \\ v\partial_x & 2u\partial_x + u_x \end{pmatrix} \]
and
\[ C_N[v, u] := \oint \frac{dz}{2\pi i} \int d\gamma \, \frac{z^N}{2}(p_+ - p_-) \]
\[ = \oint \frac{dz}{2\pi i} \int d\gamma \, \frac{z^N}{2\sqrt{v^2 + 4u}}, \]
with \( N \) being odd when \( d \) is odd.
Observe that
\[ \nabla C_N = \begin{pmatrix} \frac{\delta C_N}{\delta v} \\ \frac{\delta C_N}{\delta u} \end{pmatrix} = \begin{pmatrix} \frac{z^N v}{2\sqrt{v^2 + 4u}} \\ \frac{z^N}{\sqrt{v^2 + 4u}} \end{pmatrix}. \]

4.1 \textbf{\( R \)-matrix theory and multi-Hamiltonian structure}

The equations (52) represent a hierarchy of compatible multi-Hamiltonian systems associated to a \( R \)-matrix structure. In order to describe this property we introduce the Lie algebra \( \mathcal{G} \) with elements
\[ \alpha(z, x) = \begin{pmatrix} \alpha_1(z, x) \\ \alpha_2(z, x) \\ \alpha_3(x) \end{pmatrix}, \quad \alpha_i(\cdot, x) \in \mathbb{C}(z), \quad i = 1, 2, \]
and commutator defined by
\[
[\alpha, \beta] := \begin{pmatrix}
\alpha_{1,x}\beta_2 - \alpha_2\beta_{1,x} \\
\alpha_{2,x}\beta_2 - \alpha_2\beta_{2,x} \\
\int (\alpha_{1}\beta_{1,x} - \alpha_{1,1}\beta_{1}) \, dx
\end{pmatrix}.
\] (55)

Obviously \( \mathcal{G} \) is a central extension of its subalgebra determined by the constraint \( \alpha_3(x) \equiv 0 \). The dual space \( \mathcal{G}^* \) of \( \mathcal{G} \) is given by the set of elements of the form
\[
u(z,x) = \begin{pmatrix}
v(z,x) \\
u(z,x) \\
c(x)
\end{pmatrix}, \quad v(\cdot, x), u(\cdot, x) \in \mathbb{C}((z)),
\]
acting on \( \mathcal{G} \) according to
\[
\langle \nu, \alpha \rangle := \oint \frac{dz}{2\pi i} \left( c \alpha_3 + \int dx (v \alpha_1 + u \alpha_2) \right).
\] (56)

It is straightforward to find that the coadjoint action of \( \mathcal{G} \) on \( \mathcal{G}^* \)
\[
\langle ad^\ast \alpha(u), \beta \rangle = \langle u, [\beta, \alpha] \rangle,
\]
is given by
\[
ad^\ast \alpha(u) = \begin{pmatrix}
-2\alpha_{1,x} + (v\alpha_2)_x \\
v\alpha_{1,x} + 2u\alpha_{2,x} + u_x\alpha_2 \\
0
\end{pmatrix} = \begin{pmatrix}
J(v, u) \left( \begin{array}{c}
\alpha_1 \\
\alpha_2
\end{array} \right)
\end{pmatrix}.
\] (57)

Hence we conclude that the operator \( J(v, u) \) of (52) is the symplectic operator corresponding to the Lie-Poisson bracket of \( \mathcal{G} \).

The functionals (see (54))
\[
C_N[u] := \oint \frac{dz}{2\pi i} \int dx \frac{z^N}{2} \sqrt{v^2 + 4u},
\]
represent Casimir invariants as they satisfy
\[
J(v, u) \nabla C_N = 0.
\] (58)
Notice that in order to ensure that $\nabla C_N(u) \in \mathcal{G}$ we must restrict $C_N$ to the subset of elements of $\mathcal{G}^*$ for which degree($u^2 + 2u$) at $z \to \infty$ is even.

On the other hand, there is an infinite family of $R$-matrices in $\mathcal{G}$ of the form
\[ R_m \alpha := \frac{1}{2} \left( (z^m \alpha)_+ - (z^m \alpha)_- \right), \quad m \in \mathbb{Z}. \] (59)

They define a corresponding family of Lie-algebra structures in $\mathcal{G}$ given by
\[ [\alpha, \psi]_m = [R_m \alpha, \psi] + [\alpha, R_m \psi]. \] (60)

According to the general theory, the Casimir invariants of $(G, [\cdot, \cdot])$ are in involution
\[ \{C_N, C_M\}_m = 0, \quad N, M \geq 0, \]
with respect to all the Poisson-Lie bracket structures $(\mathcal{G}, [\cdot, \cdot])_m, m \in \mathbb{Z}$.

Therefore for each $m \in \mathbb{Z}$, there is an associated family of compatible Hamiltonian systems
\[ \partial_{t_{m,N}} u = \frac{1}{2} \left( ad^*(R_m \nabla C_N(u)) \right)(u) = \left( ad^*(z^m \nabla C_N(u))_+ \right)(u) \]
\[ = J(v, u)(z^m \nabla C_N(u))_+ = -J(v, u)(z^m \nabla C_N(u))_. \] (61)

These Hamiltonian flows are defined on the invariant submanifold $\mathcal{D}$ given by the elements $u$ of $\mathcal{G}^*$ such that
\[ d_1 \leq d_0 + 1, \quad d = \max(2d_1, d_0) = \text{even}, \] (62)
with $d_0$ and $d_1$ being the degrees of $u$ and $v$ as $z \to \infty$, respectively. Moreover, given positive integers $d_0$ and $d_1$ verifying (62) then the submanifolds $\mathcal{D}_{d_0,d_1}$ of $\mathcal{D}$ with elements of the form
\[ v = \sum_{n=0}^{d_1} v_n z^n, \quad u = \sum_{n=0}^{d_0} u_n z^n, \] (63)
are left invariant under the flows (61).

Therefore we conclude that under conditions (62) the flows (52) form a hierarchy of compatible Hamiltonian systems for $(v, u)$.

Furthermore, as a consequence of the identities
\[ \nabla C_{N+m}(u) = z^m \nabla C_N, \]
it follows that the flows (61) have an infinite number of compatible Hamiltonian formulations. On the other hand, one finds that the coadjoint action of \((G, [\cdot, \cdot]_m)\) on \(G^*\) reads
\[
2 \text{ad}^*_m \alpha (u) = J(v, u)(R_m \alpha) - z^m R(J(v, u) \alpha).
\]
In particular, (62) implies
\[
\text{ad}^*_m \alpha (u) = J(v, u)(z^m \alpha)_+ - z^m (J(v, u) \alpha_+)_+ \\
= z^m (J(v, u) \alpha_-)_- - J(v, u)(z^m \alpha_-)_-,
\]
and it means that the images of \(v\) and \(u\) under \(\text{ad}^*_m \alpha\) are polynomials in \(z\) with degrees
\[
\tilde{d}_1 = \max(m - 1, d_1 - 1), \quad \tilde{d}_2 = \max(m - 1, d_1 - 1, d_0 - 1).
\]
Therefore, for \(0 \leq m \leq d_1\) the subsets (63) determine Poisson submanifolds of \(G^*\). In this way we conclude that under conditions (62) the equations (52) not only form a hierarchy of compatible Hamiltonian systems for \((v, u)\) but also have \(d_1 + 1\) different Hamiltonian structures.

The same result holds for (52) if \(d = \max(2d_1, d_0)\) is an odd integer. To prove it one applies the above analysis to the submanifolds \(\tilde{D}_{d_0, d_1}\) of \(D\) with elements of the form
\[
v = \sum_{n=0}^{d_1} v_n z^{2n}, \quad u = \sum_{n=0}^{d_0} u_n z^{2n}. \tag{64}
\]

There are many interesting reductions of (52). For example a compatible constraint is \(v \equiv 0\). That is to say
\[
F := p^2 - u(k) = 0,
\]
so that \(p_+ = -p_-\) and (52) becomes
\[
\partial_t u = J\left(\frac{\delta C_N}{\delta u}\right)_+,
\]
where
\[
J := J(u) = 2u \partial_x + u_x,
\]
\[
C_N[u] := \oint_{\gamma} \frac{dz}{2\pi i} \int d x z^N p_+ = \oint_{\gamma} \frac{dz}{2\pi i} \int d x z^N \sqrt{u}.
\]
It can be seen that for this case our analysis lead to the Hamiltonian description obtained from the geometrical approach in [14].
4.2 Riemann invariants and gauge transformations

The discriminant of \( F = p^2 - vp - u \) is given by

\[
R(z) = -(v^2 + 4u),
\]

so that we can formulate the flows (52) in terms of the gauge invariant variable \( w := v^2 + 4u \) and the gauge variable \( \rho := v/2 \). Thus, from (53)-(54) one finds

\[
\begin{align*}
\partial_{tN} w & = (2w\partial_x + w_x) \left( \frac{z^N}{\sqrt{w}} \right)_+, \\
\partial_{tN} \rho & = -\partial_x \left( \left( \frac{z^N}{\sqrt{w}} \right)_- \rho \right)_+.
\end{align*}
\]

(65)

Observe that the variable \( w \) evolves independently of \( \rho \) and that the equation for \( \rho \) is linear in \( \rho \). This suggests the following scheme for the integration of (52): We integrate first the equation for \( w \) in terms of Riemann invariants and then we solve the linear equation for \( \rho \).

**Example**

The \( t_1 \)-flow for

\[
F := p^2 - (z + v_0)p - (z^2 + z u_1 + u_0) = 0,
\]

is

\[
\begin{align*}
\partial_t v_0 & = -\frac{1}{5\sqrt{5}}(v_{0,x} + 2 u_{1,x}), \\
\partial_t u_1 & = -\frac{1}{5\sqrt{5}}(2 v_{0,x} + 4 u_{1,x}), \\
\partial_t u_0 & = -\frac{1}{5\sqrt{5}}(2 v_0 v_{0,x} - v_0 u_{1,x} + u_{0,x}).
\end{align*}
\]

(66)

In this case, we have the gauge invariants

\[
\begin{align*}
w & := v^2 + 4u = 5z^2 + 2z w_1 + w_2, \\
w_1 & = v_0 + 2 u_1, \quad w_2 = v_0^2 + 4 u_0.
\end{align*}
\]
They are also Riemann invariants as they verify
\[ \partial_t w_i = \frac{1}{\sqrt{5}} \partial_x w_i, \quad i = 1, 2. \]
Moreover, the gauge variable \( \rho_0 := \frac{v_0}{2} \) evolves according to
\[ \partial_t \rho_0 = \frac{1}{10\sqrt{5}} \partial_x w_1. \]
In this way, the integration of (66) reduces to elementary operations.

### 4.3 Dispersionful counterpart

There is a dispersionful version of the hierarchy of flows (52) which can be described in terms of the energy-dependent spectral problem
\[ L \psi := \partial_{xx} \psi - v(k, x) \psi_x - u(k, x) \psi = 0, \tag{67} \]
where
\[ v = \sum_{i=0}^{d_1} v_i k^i, \quad u = \sum_{i=0}^{d_0} u_i k^i. \]
Indeed, the compatibility between (67) and flows of the form
\[ \partial_t \psi = a \psi + b \psi_x, \quad a, b \in \mathbb{C}[z], \]
where we are assuming (49), leads us to the following equations for \( v \) and \( u \)
\[ \partial_t \begin{pmatrix} v \\ u \end{pmatrix} = \begin{pmatrix} 2\partial_x & \partial_{xx} + \partial_x (v \cdot) \\ \partial_{xx} - v \partial_x & 2u_0 \partial_x + u_{0,x} \end{pmatrix} \begin{pmatrix} a \\ b \end{pmatrix}. \tag{68} \]
Thus we consider a Lenard relation
\[ \begin{pmatrix} -2\partial_x & \partial_{xx} + \partial_x (v \cdot) \\ -\partial_{xx} + v \partial_x & 2u_0 \partial_x + u_{0,x} \end{pmatrix} \begin{pmatrix} R \\ S \end{pmatrix} = 0, \]
which reduces to
\[ R = \frac{1}{2} (S_x + v S), \quad \tag{69} \]
\[ -\frac{1}{2} S_{xxx} + 2US_x + U_x S = 0, \]
where
\[ U := -\frac{1}{2}v_x + \frac{1}{4}v^2 + u. \]

The first equation of (69) is satisfied if
\[
\begin{pmatrix}
R \\
S
\end{pmatrix} = \begin{pmatrix}
\frac{\delta C}{\delta v} \\
\frac{\delta C}{\delta u}
\end{pmatrix},
\]

with
\[ C := C[U] = \oint \gamma \frac{dz}{2\pi i} \int d x \chi(U),\]

being a functional depending on \( U \). As for the second equation of (69), it reduces to
\[ \chi_x + \chi^2 - U = 0, \]

which in turn is satisfied by
\[ \chi = \sigma - \frac{1}{2}v, \]

with \( \sigma \) being a solution of
\[ \sigma_x + \sigma^2 - v \sigma - u = 0, \]

The last equation is verified by
\[ \sigma := \partial_x \ln \psi. \]

Therefore, we have found a quantum counterpart of the hierarchy (52)
\[
\partial_t N u = \mathcal{J} \left( \nabla H_N \right)_+, \quad N \geq 0, \tag{70}
\]

where
\[
\mathcal{J} := \begin{pmatrix}
-2\partial_x & \partial_{xx} + \partial_x (v) \\
-\partial_{xx} + v\partial_x & 2u\partial_x + u_x
\end{pmatrix}, \tag{71}
\]

and
\[ H_N[v, u] := \oint \gamma \frac{dz}{2\pi i} \int d x z^N \chi(U). \]
We notice that

\[ H_N[v, u] = \oint_{\gamma} \frac{dz}{2\pi i} \int dx \, \frac{z^N}{2} (\sigma_+ - \sigma_-), \]

where

\[ \sigma_\pm = \frac{1}{2} v \pm \chi, \]

verify

\[ L \psi = (\partial_x - \sigma_-)(\partial_x - \sigma_+). \]
