ABSTRACT. In [3] o-minimal homotopy was developed for the definable category, proving o-minimal versions of the Hurewicz theorems and the Whitehead theorem. Here, we extend these results to the category of locally definable spaces, for which we introduce homology and homotopy functors. We also study the concept of connectedness in $\mathcal{V}$-definable groups – which are examples of locally definable spaces. We show that the various concepts of connectedness associated to these groups, which have appeared in the literature, are non-equivalent.

1 Introduction

According to H.Delfs and M.Knebusch, the reference [8] is the first part of what “is designed as a topologie générale for semialgebraic geometry”. The main purpose of the book is to introduce a new category extending the semialgebraic one and large enough to be able to deal with objects such as covering maps of “infinite degree”. Specifically, the authors define locally semialgebraic spaces, roughly, as those obtained by glueing infinitely many affine semialgebraic sets.

In the o-minimal setting we have the corresponding situation, the definable category is not large enough to deal with certain natural objects. Even though the theory of locally semialgebraic spaces had not been formally extended to the o-minimal framework, some related notions have already appeared – always carrying a group structure. This is the case of $\mathcal{V}$-definable groups which were used by Y. Peterzil and S. Starchenko in [17] as a tool for the study of interpretability problems. Later, M. Edmundo introduces a restricted notion of $\mathcal{V}$-definable groups in [10] and he develops a whole theory around them. However, the latter two categories are not so flexible and general as the locally definable category. For instance, in the locally definable category there is a natural adaptation of the classical construction of universal coverings which generalize the corresponding result for restricted $\mathcal{V}$-definable groups in [11]. Another example of the rigidity of the $\mathcal{V}$-definable groups and their restricted analogues are the non-equivalent notions of connectedness introduced in [10],[11],[15] and [17] which we can now clarify by considering the locally definable category.
On the other hand, in [8], after introducing the locally semialgebraic category, locally semialgebraic homotopy theory is developed. Delfs and Knebusch first prove — using the Tarski-Seidenberg principle — some beautiful results relating both the semialgebraic and the classical homotopy of semialgebraic sets defined without parameters — and hence realizable over the reals. Then, they generalize these results to regular paracompact locally semialgebraic spaces — the nice ones. Because of the lack of the Tarski-Seidenberg principle in o-minimal structures, only the o-minimal fundamental group was considered (see [6]) with strong consequences in the study of definable groups in [12]. In [3], the authors fill this gap — in the study of definable homotopy — by relating both the o-minimal and the semialgebraic (higher) homotopy groups. The core of the latter work is the adaptation to the o-minimal setting of some techniques used in [8] via a refinement of the Triangulation theorem (see the Normal Triangulation Theorem in [1]).

Having at hand these recent results for the o-minimal homotopy theory, it seems to us natural to extend them to the locally definable category. Therefore, we have taken this opportunity to develop the locally definable category in o-minimal structures expanding a real closed field. Furthermore, we have tried to unify the related notions of $\bigvee$-definable groups and their restricted version via the theory of locally definable spaces. We also point out that we have avoided the presentation style of Delfs and Knebusch in [8] with “sheaf” flavour, using instead the natural generalization of definable spaces of L. van den Dries in [9].

The results of this paper have already been applied to prove the contractibility of the universal covering group of a definably compact abelian group (see [5]).

In Section 2 we first introduce the category of locally definable spaces (in short ld-spaces). Locally definable spaces of special interest are the regular paracompact ones (in short LD-spaces). We collect the relevant facts from [8] which can be directly adapted to our context, most notably the Triangulation Theorem for LD-spaces. In [17] it is implicitly proved that the $\bigvee$-definable groups are examples of ld-spaces. In Section 3 we prove that the restricted ones are moreover paracompact —and hence LD-spaces— and we also discuss other examples of ld-spaces. In Section 4 we deal with connectedness for ld-spaces and we clarify the relation among the different notions of connectedness used for $\bigvee$-definable groups which appear in the literature. A homology theory for LD-spaces is developed in Section 5 via an alternative approach to that of [8] for locally semialgebraic spaces (which goes through sheaf cohomology). Finally, with all these tools at hand, we prove in Section 6 the generalizations to LD-spaces of the homotopy results in [3], in particular the Hurewicz theorems and the Whitehead theorem.

We will work over an o-minimal expansion of a real closed field. However, for some of the results the presence of a field can be weakened, namely when we do not use triangulations. We have added a Omitting the r.c.f.
The rest of the sections, i.e., Section 5 and Section 6, deal with LD-spaces. The main reason to consider LD-spaces is that we are able to triangulate them, hence the assumption of having a real closed field is needed to make sense of the complexes.

The results of this paper are part of the first author’s Ph.D. dissertation. The proofs of the results below stated as Facts are adaptations of the corresponding ones in the semialgebraic context, their complete proofs in the o-minimal setting can be found in [2, Ch.3].

2 Preliminaries on locally definable spaces

We fix an o-minimal expansion \( \mathcal{R} \) of a real closed field \( R \). We take the order topology on \( R \) and the product topology on \( R^n \) for \( n > 1 \). For the rest of this paper, “definable” means “definable with parameters” and “definable map” means “continuous definable map”, unless otherwise specified.

We shall briefly discuss the category of locally definable spaces. All the results we list in this section are analogous to those of locally semialgebraic spaces in [8]. The proofs of these results in [8] are based on properties of semialgebraic sets which are shared by definable sets. Hence we have not included their proofs here (see also [2, Ch.3]).

Definition 2.1. Let \( M \) be a set. An atlas on \( M \) is a family of charts \( \{(M_i, \phi_i)\}_{i \in I} \), where \( M_i \) is a subset of \( M \) and \( \phi_i : M_i \to Z_i \) is a bijection between \( M_i \) and a definable set \( Z_i \) of \( \mathbb{R}^{n(i)} \) for all \( i \in I \), such that \( M = \bigcup_{i \in I} M_i \) and for each pair \( i, j \in I \) the set \( \phi_i(M_i \cap M_j) \) is a relative open definable subset of \( Z_i \) and the map

\[
\phi_{ij} := \phi_j \circ \phi_i^{-1} : \phi_i(M_i \cap M_j) \to M_i \cap M_j \to \phi_j(M_i \cap M_j)
\]

is definable. We say that \( (M, M_i, \phi_i)_{i \in I} \) is a locally definable space. The dimension of \( M \) is \( \text{dim}(M) := \sup \{\text{dim}(Z_i) : i \in I\} \) (an integer \( \geq 0 \) or \( \infty \)). If \( Z_i \) and \( \phi_{ij} \) are defined over \( A \) for all \( i, j \in I \), we say that \( M \) is a locally definable space over \( A \).

We say that two atlases \( (M, M_i, \phi_i)_{i \in I} \) and \( (M, M_i', \psi_j)_{j \in J} \) on a set \( M \) are equivalent if and only if for all \( i \in I \) and \( j \in J \) we have that (i) \( \phi_i(M_i \cap M_i') \) and \( \psi_j(M_i \cap M_i') \) are relative open definable subsets of \( \phi_i(M_i) \) and \( \psi_j(M_i') \) respectively, (ii) the map \( \psi_j \circ \phi_i^{-1} : \phi_i(M_i \cap M_i') \to M_i \cap M_i' \to \psi_j(M_i \cap M_i') \) and its inverse are definable and (iii) \( M_i \subset \bigcup_{k \in I_0} M'_k \) and \( M_i' \subset \bigcup_{s \in I_0} M'_s \) for some finite subsets \( I_0 \) and \( I_0 \) of \( J \) and \( I \) respectively.

Note that in the above definition if we take \( I \) to be finite then \( M \) is just a definable space in the sense of [9]. In fact, some of the notions that we are going to introduce in this section are generalizations of the corresponding ones in the category of definable spaces.
Even though the above definition seems different from its semialgebraic analogue (see [8, Def.I.3]), they are actually equivalent. In [8] it is (implicitly) proved that Definition I.3 is equivalent to the semialgebraic analogue of our definition here (see [8, Lem.I.2.2] and the remark after [8, Lem.I.2.1]). The same proofs can be adapted to the o-minimal setting.

Given a locally definable space \((M, M_i, \phi_i)\), there is a unique topology in \(M\) for which \(M_i\) is open and \(\phi_i\) is a homeomorphism for all \(i \in I\). For the rest of the paper any topological property of locally definable spaces refers to this topology. We are mainly interested in Hausdorff topologies. Henceforth, an \textbf{ld-space} means a Hausdorff locally definable space.

We now introduce the subsets of interest in the category of \textbf{ld-spaces}.

**Definition 2.2.** Let \((M, M_i, \phi_i)_{i \in I}\) be an ld-space. We say that a subset \(X\) of \(M\) is a \textbf{definable subspace} of \(M\) (over \(A\)) if there is a finite \(J \subset I\) such that \(X \subset \bigcup_{j \in J} M_j\) and \(\phi_j(M_j \cap X)\) is definable (resp. over \(A\)) for all \(j \in J\). A subset \(Y \subset M\) is an \textbf{admissible subspace} of \(M\) (over \(A\)) if \(\phi_i(Y \cap M_i)\) is definable (resp. over \(A\)) for all \(i \in I\), or equivalently, \(Y \cap X\) is a definable subspace of \(M\) (resp. over \(A\)) for every definable subspace \(X\) of \(M\) (resp. over \(A\)).

The admissible subspaces of an ld-space are closed under complements, finite unions and finite intersections. Moreover, the interior and the closure of an admissible subspace is an admissible subspace.

Every definable subspace of an ld-space is admissible. The definable subspaces of an ld-space are closed under finite unions and finite intersections, but not under complements. The interior of a definable subspace is a definable subspace. However, the closure of a definable subspace might not be a definable subspace (see Example 3.2).

**Remark 2.3.** Given an ld-space \((M, M_i, \phi_i)_{i \in I}\) we have that every admissible subspace \(Y\) of \(M\) inherits in a natural way a structure of an ld-space, whose atlas is \((Y, Y_i, \psi_i)_{i \in I}\), where \(Y_i := M_i \cap Y\) and \(\psi_i := \phi_i|_{Y_i}\). In particular, if \(Y\) is a definable subspace then it inherits the structure of a definable space.

Now, we introduce the maps that we will use in the locally definable category. First, note that given two ld-spaces \(M\) and \(N\), with their atlas \((M_i, \phi_i)_{i \in I}\) and \((N_j, \psi_j)_{j \in J}\), respectively, the atlas \((M_i \times N_j, (\phi_i, \psi_j))_{i \in I, j \in J}\) makes \(M \times N\) into an ld-space. In particular, if \(M\) and \(N\) are definable spaces, then \(M \times N\) is a definable space. Recall that a map \(f\) from a definable space \(M\) into a definable space \(N\) is a definable map over \(A\), \(A \subset R\), if its graph is a definable subset of \(M \times N\) over \(A\).

**Definition 2.4.** Let \((M, M_i, \phi_i)_{i \in I}\) and \((N, N_j, \phi_j)_{j \in J}\) be ld-spaces. A map \(f : M \rightarrow N\) is an \textbf{ld-map} (over a subset \(A\) of \(R\)) if \(f(M_i)\) is a definable
subspace of $N$ and the map $f|_{M_i} : M_i \to f(M_i)$ is definable (resp. over $A$) for all $i \in I$.

The behavior of admissible subspaces and ld-maps in the locally definable category is different from that of definable subsets and definable maps in the definable category. For, even though the preimage of an admissible subspace by an ld-map is an admissible subspace, the image of an admissible subspace by an ld-map might not be an admissible subspace (see comments after Example 3.1). Nevertheless, the image of a definable subspace by an ld-map is a definable subspace. In particular, let us note that every ld-map between definable spaces is a definable map and therefore the category of definable spaces is a full subcategory of the category of ld-spaces. On the other hand, given two ld-spaces $M$ and $N$, the graph of an ld-map $f : M \to N$ is an admissible subspace of $M \times N$. However, not every continuous map $f : M \to N$ whose graph is admissible in $M \times N$ is an ld-map.

The notion of connectedness in the locally definable category which we now introduce is a subtle issue. It extends the natural concept of “definably connected” for definable spaces. In Section 4 below we will analyze this concept and we will compare it with other definitions introduced by different authors in the study of $\bigvee$-definable groups.

**Definition 2.5.** Let $M$ be an ld-space and $X$ an admissible subspace of $M$. We say that $X$ is connected if there is no admissible subspace $U$ of $M$ such that $X \cap U$ is a nonempty proper clopen subset of $X$.

In Section 4 we also deal with path-connectedness as well as with connected and path connected components.

We now introduce ld-spaces with some special properties. As we will see below, in the ld-spaces with these properties there is a good relation between the topological and the definable settings. Moreover, they form an adequate framework to develop a homotopy theory.

We say that an ld-space $(M, M_i, \phi_i)$ is **regular** if every $x \in M$ has a fundamental system of closed (definable) neighbourhoods, i.e., for every open $U$ of $M$ with $x \in U$ there is a closed (definable) subspace $C$ of $M$ such that $C \subset U$ and $x \in \text{int}(C)$. Equivalently, an ld-space $M$ is regular if for every closed subset $C$ of $M$ and every point $x \in M \setminus C$ there are open (admissible) disjoint subsets $U_1$ and $U_2$ with $C \subset U_1$ and $x \in U_2$.

**Remark 2.6.** If $M$ is a regular ld-space then every definable subspace of $M$ can be considered as an affine set, i.e, as a definable set of $R^n$ for some $n \in \mathbb{N}$. For, suppose that $X$ is a definable subspace of $M$. Then, $X$ inherits a structure of definable space from $M$ (see Remark 2.3). Since $M$ is regular then $X$ is also regular. Finally, by the $\omega$-minimal version of Robson’s embedding theorem, $X$ is affine (see [9, Ch.10, Thm. 1.8]).
Let \((M, M_i, \phi_i)_{i \in I}\) be an ld-space. A family \(\{X_j\}_{j \in J}\) of admissible subspaces of \(M\) is an admissible covering of \(X := \bigcup_{j \in J} X_j\) if for all \(i \in I\), \(M_i \cap X = M_i \cap (X_{j_1} \cup \cdots \cup X_{j_l})\) for some \(j_1, \ldots, j_l \in J\) (note that in particular \(X\) is an admissible subspace). A family \(\{Y_j\}_{j \in J}\) of admissible subspaces of \(M\) is locally finite if for all \(i \in I\) we have that \(M_i \cap Y_j \neq \emptyset\) for only a finite number of \(j \in J\) (note that in particular it is an admissible covering of their union). In general, not every admissible covering is locally finite (see Example 3.2). We say that an ld-space \(M\) is paracompact if there exists a locally finite covering of \(M\) by open definable subspaces. Note that this notion is “weaker” than the classical one. It is easy to prove that if \(M\) is paracompact then every admissible covering of \(M\) has a locally finite refinement (see [8, Prop. I.4.5]). We say that an ld-space \(M\) is Lindelöf if there exist an admissible covering of \(M\) by countably many open definable subspaces.

Paracompactness provides us with a good relation between the topological and definable setting.

**Fact 2.7.** Let \(M\) be an ld-space.
1. [8, Prop. I.4.6] If \(M\) is paracompact then for every definable subspace \(X\), the closure \(\bar{X}\) is also a definable subspace of \(M\).
2. [8, Thm. I.4.17] If \(M\) is connected and paracompact then \(M\) is Lindelöf.
3. [8, Prop. I.4.18] If \(M\) is Lindelöf and for every definable subspace \(X\) its closure \(\bar{X}\) is also a definable subspace, then \(M\) is paracompact.
4. [8, Prop. I.4.7] If \(M\) is paracompact and every open definable subspace of \(M\) is regular then \(M\) is regular.

Let us study the behavior of ld-spaces with respect to model theoretic operators. Firstly, let us show that given an elementary extension \(R_1\) of an o-minimal structure \(R\) and given an ld-space \(M\) in \(R\), there is a natural realization \(M(R_1)\) of \(M\) over \(R_1\) as an ld-space. For, denote by \(\{\phi_i : M_i \to Z_i\}_{i \in I}\) the atlas of \(M\) and consider the set \(Z = \bigcup_{i \in I} Z_i/\sim\), where \(x \sim y\) for \(x \in Z_i\) and \(y \in Z_j\) if and only if \(\phi_{ij}(x) = y\). Note that we can define an ld-space structure on \(Z\) in a natural way and that \(Z\) with this ld-space structure is isomorphic to \(M\) (see Definition 2.4). Now, we define the realization \(Z(R_1)\) as the ld-space whose underlying set is \(\bigcup_{i \in I} Z_i(R_1)\) modulo the relation \(x \sim_{R_1} y\) for \(x \in Z_i(R_1)\) and \(y \in Z_j(R_1)\) if and only if \(\phi_{ij}(R_1)(x) = y\), and with the obvious atlas. If \(X\) is a (admissible) definable subspace of \(M\) then \(X(R_1)\) is clearly a (resp. admissible) definable subspace of \(M\) in \(R_1\). The following result concerning the behaviour of several properties under elementary extensions is an adaptation of those from [8].

**Fact 2.8.** Let \(R_1\) be an elementary extension of \(R\) and let \(M\) be an ld-space in \(R\). Then,
1. \(M\) is connected if and only if \(M(R_1)\) is connected,
(ii) $M$ is Lindelöf if and only if $M(\mathcal{R}_1)$ is Lindelöf,
(iii) $M$ is paracompact if and only if $M(\mathcal{R}_1)$ is paracompact,
(iv) $M$ is regular and paracompact if and only if $M(\mathcal{R}_1)$ is regular and paracompact.

Proof. Let $(M_i, \phi_i)_{i \in I}$ be an atlas of $M$. (i) For the nontrivial part, note that the connected components (see section 4) of the ld-space $M(\mathcal{R}_1)$ are actually defined over $\mathcal{R}$. (ii) It is enough to note that a Lindelöf ld-space is covered by a countable subcovering of its atlas. (iii) For the nontrivial part, by (i), (ii) and Fact 2.7, it suffices to prove that for all definable subspace $X$ of $M$ the closure $\overline{X}$ is also a definable subspace of $M$, i.e., $\overline{X}$ is contained in a finite union of $M_i$'s. Indeed, given a definable subspace $X$ of $M$, the latter follows from the fact that $X(\mathcal{R}_1) = \overline{X}(\mathcal{R}_1)$ is contained in a finite union of $M_i(\mathcal{R}_1)$'s by Fact 2.7.(1). (iv) By (iii) and Fact 2.7.(4), this follows from the fact that every finite union of $M_i$'s is regular if and only if every finite union of $M_i(\mathcal{R}_1)$'s is regular.

On the other hand, note that given an o-minimal expansion $\mathcal{R}'$ of $\mathcal{R}$ and an ld-space $M$ in $\mathcal{R}$, we can consider $M$ as an ld-space in $\mathcal{R}'$. Clearly, if $X$ is a (admissible) definable subspace of $M$ in $\mathcal{R}$ then $X$ is a (resp. admissible) definable subspace of $M$ in $\mathcal{R}'$.

Proposition 2.9. Let $\mathcal{R}'$ be an o-minimal expansion of $\mathcal{R}$ and let $M$ be an ld-space in $\mathcal{R}$. Then,

(i) $M$ is regular in $\mathcal{R}$ if and only if it is regular in $\mathcal{R}'$,
(ii) $M$ is connected in $\mathcal{R}$ if and only if it is connected in $\mathcal{R}'$,
(iii) $M$ is Lindelöf in $\mathcal{R}$ if and only if it is Lindelöf in $\mathcal{R}'$,
(iv) $M$ is paracompact in $\mathcal{R}$ if and only if it is paracompact in $\mathcal{R}'$.

Proof. (i) This follows from the fact that an ld-space is regular if and only if each point has a fundamental system of closed neighbourhoods.
(ii) If $M$ is connected in $\mathcal{R}'$ then it is clearly connected in $\mathcal{R}$. On the other hand, if $M$ is connected in $\mathcal{R}$ then by Fact 4.2 any two points are connected by an ld-path definable in $\mathcal{R}$. In particular, any two points are connected by an ld-path definable in $\mathcal{R}'$ and hence, again by Fact 4.2, $M$ is connected in $\mathcal{R}'$.
(iii) Let us show that if $M$ is Lindelöf in $\mathcal{R}'$ then $M$ is Lindelöf in $\mathcal{R}$ (the converse is trivial). Indeed, let $(M_i, \phi_i)_{i \in I}$ be an atlas of $M$ in $\mathcal{R}$ and let $\{U_n : n \in \mathbb{N}\}$ be a countable admissible covering of $M$ by open definable subspaces in $\mathcal{R}'$ of $M$. Since each $U_n$ is a definable subspace, it is contained in a finite union of charts $M_i$. Therefore, there exists a countable subcovering of $\{M_i : i \in I\}$ which already covers $M$ and hence $M$ is Lindelöf in $\mathcal{R}$.
(iv) Let us show that if $M$ is paracompact in $\mathcal{R}'$ then $M$ is paracompact in $\mathcal{R}$ (the converse is trivial). Without loss of generality we can assume that $M$ is connected. Therefore, by the above equivalences and Fact 2.7.(2), $M$
is Lindelöf in \( R \). Then, by Fact 2.7.(3), it suffices to prove that for every definable subspace \( X \) of \( M \) in \( R \), its closure \( \overline{X} \) is also a definable subspace of \( M \) in \( R \). Since \( M \) is paracompact in \( R' \), the latter is clear by Fact 2.7.(1).

The fact that definable subspaces are affine together with paracompactness permits to establish a Triangulation Theorem for regular and paracompact ld-spaces (which will be essential for the proof of the Hurewicz and Whitehead theorems below). Fix a cardinal \( \kappa \). We denote by \( R^\kappa \) the \( R \)-vector space generated by a fixed basis of cardinality \( \kappa \). A \textbf{generalized simplicial complex} \( K \) in \( R^\kappa \) is a usual simplicial complex except that we may have infinitely many (open) simplices (see [8, Def.I.3]). The \textbf{locally finite} generalized simplicial complexes are those ones for which the star of each simplex is a finite subcomplex. On the latter we can define in an obvious way an ld-space structure. Indeed, given a locally finite generalized simplicial complex \( K \), for each \( \sigma \in K \) we have that \( St_K(\sigma) \) is a finite subcomplex and therefore \( St_K(\sigma) \subset R^{n_\sigma} \subset R^\kappa \) for some \( n_\sigma \in \mathbb{N} \). Now, giving each \( St_K(\sigma) \) the topology it inherits from \( R^{n_\sigma} \), it suffices to consider the atlas \( \{(St_K(\sigma), id|_{St_K(\sigma)})\}_{\sigma \in K} \). With this ld-space structure, a locally finite generalized simplicial complex is regular and paracompact (see Fact 2.7.(4)). Henceforth, all the locally definable concepts about locally finite generalized simplicial complexes refer to the aforementioned regular and paracompact ld-space structure. As in the definable setting, it is easy to prove that a locally finite generalized simplicial complex \( K \) is connected if and only if there is no proper nonempty subcomplex \( L \) of \( K \) such that \( |L| \) (which is clearly an admissible subspace) is both open and closed in \( |K| \).

The next result is a sort of converse of the fact that locally finite generalized simplicial complexes are regular and paracompact ld-spaces.

**Fact 2.10 (Triangulation Theorem).** [8, Thm. II.4.4] Let \( M \) be a regular and paracompact ld-space and let \( \{A_j : j \in J\} \) be a locally finite family of admissible subspaces of \( M \). Then, there exists an ld-triangulation of \( M \) partitioning \( \{A_j : j \in J\} \), i.e., there is a locally finite generalized simplicial complex \( K \) and an ld-homeomorphism \( \psi : |K| \rightarrow M \), where \( |K| \) is the realization of \( K \), such that \( \psi^{-1}(A_j) \) is the realization of a subcomplex of \( K \) for every \( j \in J \).

**Remark 2.11.** As in the definable case, we can always suppose in the Triangulation theorem that the vertices of the generalized simplicial complex \( K \) are tuples of real algebraic numbers. Indeed, if we consider a generalized simplicial complex \( K \), seen as an abstract one, with set of vertices of cardinality \( \kappa \), there is a “canonical realization” of \( K \) in \( R^\kappa \) whose vertices are the standard basis of \( R^\kappa \). Moreover, if the ld-space \( M \) is defined over some subset \( A \) of \( R \), then the locally definable homeomorphism \( \psi \) may be defined over \( A \).
A key step in the proof of the aforementioned fact consists in embedding the given regular and paracompact ld-space in another one with the following good property. We say that an ld-space $M$ is **partially complete** if every closed definable subspace $X$ of $M$ is definably compact, i.e., every definable curve in $X$ is completable in $X$.

**Fact 2.12.** [8, Thm. II.2.1] Let $M$ be a regular and paracompact ld-space. Then, there exist an embedding of $M$ into a partially complete regular and paracompact ld-space, i.e, there is partially complete regular and paracompact ld-space $N$ and an ld-map $i : M \rightarrow N$ such that $i(M)$ is an admissible subspace of $N$ and $i : M \rightarrow i(M)$ is an ld-homeomorphism (where $i(M)$ has the structure of regular and paracompact ld-space inherited from $M$).

Henceforth, we denote a regular and paracompact ld-space by **LD-space**.

Note that by Fact 2.7.(2) a connected LD-space is Lindelöf.

### 3 Examples of locally definable spaces

We begin this section discussing some natural examples of subsets of $R^n$ carrying a special ld-space structure. In the second subsection we will consider $\bigvee$-definable groups as ld-spaces. Another important class of examples will be shown in Section 6.2, where we prove the existence of covering maps for LD-spaces.

#### 3.1 Subsets of $R^n$ as ld-spaces

**Example 3.1.** Fix an $n \in \mathbb{N}$ and a collection $\{M_i\}_{i \in I}$ of definable subsets of $R^n$ such that $M_i \cap M_j$ is open in both $M_i$ and $M_j$ (with the topology they inherit from $R^n$) for all $i, j \in I$. Then, clearly $(M_i, \text{id}|_{M_i})_{i \in I}$ is an atlas for $M := \bigcup_{i \in I} M_i$ and hence $M$ is an ld-space.

Let $M \subset R^n$ be an ld-space as in Example 3.1. Then it is easy to prove that a definable subspace of $M$ is a definable subset of $R^n$. However, consider the particular example where $M_i := (-i, i) \subset R$ for $i \in \mathbb{N}$, so that $M = \bigcup_{i \in \mathbb{N}} M_i = \text{Fin}(R)$. Note that if $R = \mathbb{R}$ then $\mathbb{R}$ is not a definable subspace of $\text{Fin}(\mathbb{R})$ ($= \mathbb{R}$). This also shows that the structures of $\mathbb{R}$ as ld-space and definable set are different. The latter example can be used also to show that the image of an admissible subspace of an ld-space by an ld-map might not be admissible. For, take $R$ a non-archimedean real closed field and the ld-map $\text{id} : \text{Fin}(R) \rightarrow R : x \mapsto x$. Clearly, $\text{Fin}(R)$ is not an admissible subspace of $R$ since the admissible subspaces of $R$ are exactly the definable ones.

Nevertheless, we point out that if $M \subset R^n$ is as in Example 3.1 with each $M_i$ defined over $A$, $A \subset R$, $|A| < \kappa$, and $\mathcal{R}$ is $\kappa$-saturated, then a
definable subset of $R^n$ contained in $M$ is a definable subspace of $M$. For, if $X \subset M$ is a definable subset, to prove that it is a definable subspace it suffices to show that it is contained in a finite union of charts $M_i$, which is clear by saturation.

In general, the topology of an ld-space $M \subset R^n$ as in Example 3.1 does not coincide with the topology it inherits from $R^n$. Consider the following example in $\mathbb{R}$. Take $M_0 := \{0\}$ and $M_i := \{\frac{1}{i}\}$ for $i \in \mathbb{N} \setminus \{0\}$. $M_0$ is open in the topology of $M$ as ld-space but it is non-open with the topology that $M$ inherits from $\mathbb{R}$. It is well known that this also happen at the definable space level (see Robson’s example of a non-regular semialgebraic space –Chapter 10 in [9]–). Moreover, Robson’s example shows that even in the presence of saturation the topologies might not coincide.

Finally, assume that $\mathcal{R}$ is $\kappa$-saturated and let $M \subset R^n$ is as in Example 3.1 with each $M_i$ defined over $A$, $A \subset \mathbb{R}$, $|A| < \kappa$. As we have seen above, in this case a subset $X$ of $M$ is a definable subspace of $M$ if and only if $X$ is a definable subset of $R^n$. Furthermore, assume that the topology of $M$ as ld-space coincides with the topology it inherits from $R^n$. Then clearly a definable subset $X \subset R^n$ with $X \subset M$ is definably connected if and only if it is connected. Indeed, a set $U \subset R^n$ is a proper clopen definable subset of $X$ if and only if is a proper clopen definable subspace of $X$.

Next, we show that an ld-space $M$ as in Example 3.1 might not be paracompact.

**Example 3.2.** Let $M$ be as in Example 3.1 with $M_i = \{(x, y) \in R^2 : y < 0\} \cup \{(x, y) \in R^2 : x = i\}$ for each $i \in \mathbb{N}$. The set $X = \{(x, y) \in R^2 : y < 0\}$ is a definable subspace of $M = \bigcup_{i \in \mathbb{N}} M_i \subset R^2$. However, $X = X \cup \{(i, 0) \in R^2 : i \in \mathbb{N}\}$ is not a definable subspace of $M$. In particular, $M$ is not paracompact (see Fact 2.7.(1)).

We finish by showing that another class of subsets that classically has been considered as “locally semialgebraic subsets” (for example, by S. Łojasiewicz) can be treated inside the theory of ld-spaces.

**Example 3.3.** Let $M$ be a subset of $R^n$ such that for every $x \in M$ there is an open definable neighbourhood $U_x$ of $x$ in $R^n$ with $U_x \cap M$ definable subset. Let $M_x := U_x \cap M$ for each $x \in M$. Then $M$ is an ld-space with the atlas $(M_x, id|_{M_x})_{x \in M}$.

Using the notation of Example 3.3, it is clear that $M_x \cap M_y$ is definable and open in both $M_x$ and $M_y$ for all $x, y \in M$ and therefore $M$ is an ld-space as in Example 3.1. Moreover, the topology of $M$ as ld-space equals the one it inherits from $R^n$.

### 3.2 $\forall$-definable groups

**Throughout this section we will assume $\mathcal{R}$ is $\aleph_1$-saturated.** The $\forall$-definable groups have been considered by several authors as a tool for the study of
definable groups in o-minimal structures. Y. Peterzil and S. Starchenko
give the following definition in [17]. A group \((G,\cdot)\) is a \(\mathcal{V}\)-definable group
over a subset \(A\) of \(R\), if \(|A| < \aleph_1\) and there is a collection \(\{X_i : i \in I\}\) of
definable subsets of \(R^n\) over \(A\) such that \(G = \bigcup_{i \in I} X_i\) and for every \(i, j \in I\)
there is \(k \in I\) such that \(X_i \cup X_j \subset X_k\) and the restriction of the group
multiplication to \(X_i \times X_j\) is a (not necessarily continuous) definable map
into \(R^n\). M. Edmundo introduces in [10] a notion of restricted \(\mathcal{V}\)-definable
group which he calls “locally definable” group. Our purpose in this section
is to include both notions within the theory of ld-spaces.

In [17], some (topological) topics of \(\mathcal{V}\)-definable groups are discussed to
study the definable homomorphisms of abelian groups in o-minimal structures
and, in particular, they prove the following result.

**Fact 3.4.** [17, Prop. 2.2] Let \(G \subset R^n\) be a \(\mathcal{V}\)-definable group. Then, there
is a uniformly definable family \(\{V_a : a \in S\}\) of subsets of \(G\) containing the
identity element \(e\) and a topology \(\tau\) on \(G\) such that \(\{V_a : a \in S\}\) is a basis
for the \(\tau\)-open neighbourhoods of \(e\) and \(G\) is a topological group. Moreover,
every generic \(h \in G\) has an open neighbourhood \(U \subset N^n\) such that \(U \cap G\)
is \(\tau\)-open and the topology which \(U \cap G\) inherits from \(\tau\) agrees with the
topology it inherits from \(R\), and the topology \(\tau\) is the unique one with the
above properties.

Because of the above fact is natural to introduce the following concept.

**Definition 3.5.** We say that a group \((G,\cdot)\) is an ld-group if \(G\) is an ld-space
and both \(\cdot : G \times G \to G\) and \(-1 : G \to G\) are ld-maps. If \(G\) is
moreover paracompact as ld-space we say that \(G\) is an LD-group (note that
since every ld-group is a topological group it is regular).

**Remark 3.6.** (i) Every ld-group \(G\) is regular because it is a topological
group. We recall the standard proof. Let \(g \in G\) and let \(U\) be an open
neighbourhood of \(g\) in \(G\). We show that there is an open neighbourhood \(V\)
of \(g\) such that \(V \subset U\). Firstly, since \(G \to G : x \mapsto g^{-1}x\) is a homeomorphism,
without loss of generality we can assume that \(g = e\), where \(e\) is the identity
element of \(G\). Now, since \(\cdot : G \times G \to G\) is continuous and \(ee^{-1} = e\), there is
an open neighbourhood \(V\) of \(e\) such that \(VV^{-1} \subset U\). We prove that \(V \subset U\).
Let \(y \in V\). Since \(yV\) is an open neighbourhood of \(y\) in \(G\), we have that
\(yV \cap V \neq \emptyset\). Therefore, \(y \in VV^{-1} \subset U\), as required.
(ii) We show that the dimension of an ld-group \(G\) is finite. Given \(g \in G\), we
define \(\dim_G(g)\) as the least integer \(n\) such that there is an open definable
subspace \(U\) of \(G\) of dimension \(n\) with \(g \in U\). Clearly, \(\dim_G(g) \leq \dim(G)\)
for every \(g \in G\) and \(\dim(G) = \sup\{\dim_G(g) : g \in G\}\). We show that
\(\dim_G(g) = \dim_G(h)\) for all \(g, h \in G\). Fix \(g, h \in G\). By symmetry, it
suffices to show that \(\dim_G(g) \leq \dim_G(h)\). Let \(U\) be an open definable
subspace of \(G\) such that \(h \in U\) and \(\dim(U) = \dim_G(h)\). Since the map
$G \rightarrow G : x \mapsto gh^{-1}x$ is an ld-isomorphism, we have that $gh^{-1}U$ is an open definable subspace of $G$ with $g \in gh^{-1}U$ and $\dim(gh^{-1}U) = \dim(U)$. We deduce that $\dim_G(g) \leq \dim(gh^{-1}U) = \dim(U) = \dim_G(h)$, as required. Finally, we have that $\dim(G) = \sup\{\dim_G(g) : g \in G\} = \dim_G(h)$ for some (any) $h \in G$, so that $\dim(G)$ is finite.

We will see that every $\forall$-definable group (with its group topology) is an ld-group. We begin with the following result.

**Lemma 3.7.** Let $G \subset R^n$ be a $\forall$-definable group over $A$ and let $\tau$ be the topology of Fact 3.4. Then, for every generic $g \in G$ there is a definable over $A$ subset $U_g \subset G$ which is $\tau$-open and such that the topology which $U_g$ inherits from $\tau$ agrees with the topology it inherits from $R^n$.

**Proof.** By Fact 3.4 it suffices to prove that the parameter set $A$ is preserved. Write $G = \bigcup_{i \in I} X_i$. The dimension of $G$ is defined as $\max\{\dim(X_i) : i \in I\}$. Fix an $X_i$ of maximal dimension and a generic $g \in X_i$. We can assume that $X_i^{-1} = X_i$. Let $X_j$ be such that $X_i X_j \subset X_j$. All the definable sets we shall consider in the proof are definable subsets of $X_j$. For each $a \in X_i$ we consider the definable set

$$W_a = \{x \in X_i : \forall \delta > 0 \exists \epsilon > 0 \ B(x, \epsilon) \subset x a^{-1} B(a, \delta) \land$$

$$\forall \epsilon > 0 \exists \delta > 0 \ xa^{-1} B(a, \delta) \subset B(x, \epsilon)\},$$

where $B(x, \epsilon) = \{y \in X_i : |y - x| < \epsilon\}$. We also consider the definable set

$$V = \{y \in X_i : W_g \text{ is large in } X_i\}.$$

By Claim 2.3 of [17, Prop. 2.2], for every $h \in X_i$ generic over $A, g$ we have that $h \in W_g$ and therefore $g \in V$. Moreover, since $g$ is generic, we have that $g \in U := int_{X_i \setminus V}(V)$ (the interior with respect to the topology of the ambient space $R^n$), which is a definable over $A$ subset of $X_i$. Fix $a \in U$. We shall prove that

(i) for every $\epsilon > 0$ there is $\delta > 0$ such that $ag^{-1}B(g, \delta) \subset B(a, \epsilon)$, and

(ii) for every $\epsilon > 0$ there is $\delta > 0$ such that $ga^{-1}B(a, \delta) \subset B(g, \epsilon)$.

Granted (i) and (ii), note that $U_g := U$ is the desired neighbourhood of $g$. Let us show (i). Consider a generic $h \in X_i$ over $A, a$. Since $h \in W_a$, there is $\delta > 0$ such that $ah^{-1}B(h, \delta) \subset B(a, \epsilon)$. By Claim 2.3 of [17, Prop. 2.2], there is $\delta > 0$ such that $g^{-1}B(g, \delta) \subset h^{-1}B(h, \delta)$. Hence $ag^{-1}B(g, \delta) \subset ah^{-1}B(h, \delta) \subset B(a, \epsilon)$. The proof of (ii) is similar. \[\square\]

The following technical fact can be easily deduced from the proof of [10, Prop 2.11].

**Fact 3.8.** Let $G = \bigcup_{i \in I} X_i$ be an $\forall$-definable group over $A$. Let $V = \bigcup_{k \in \Lambda} V_k$ (directed union) be a subset of $G$ such that each $V_k$ is definable
over $A$ and $V$ is large in $G$, i.e., every generic point of $G$ is contained in $V$. Then there is a collection of elements $\{b_j \in G : j \in J\}$ with each $b_j$ definable over $A$, such that each $X_i$ is contained in a finite union of subsets of the form $b_j V_k$. In particular, $G = \bigcup_{j \in J} b_j V$.

As it was pointed out by Y. Peterzil to us, a stronger version of the above fact can be proved. In particular, and using the notation of Fact 3.8, there exist $b_0, \ldots, b_n \in G$, $n = \dim(G)$, such that $G = \bigcup_{i=0}^n b_i V$ (it is enough to adapt the proof of [16, Fact. 4.2]). However, in this case we do not know if $b_0, \ldots, b_n$ are definable over $A$. Since we are interested in preserving the parameter set we will use the above Fact 3.8.

**Theorem 3.9.** Let $G \subset R^n$ be a $\forall$-definable group over $A$. Let $A \subset C \subset R$. Then

(i) $G$ with its group topology (from Fact 3.4) is an ld-group over $A$,

(ii) a subset $X$ of $G$ is a definable subset of $R^n$ over $C$ if and only if it is a definable subspace of $G$ over $C$, and

(iii) given a definable subspace $X$ of $G$ over $C$, its closure $\overline{X}$ (with respect to the group topology) is a definable subspace of $G$ over $C$.

**Proof.** (i) Let $\mathcal{G}$ be the collection of all generics points of $G$. For each $g \in \mathcal{G}$, let $U_g$ be the definable over $A$ subset of $G$ of Lemma 3.7. Consider the subset $V = \bigcup_{g \in \mathcal{G}} U_g$ of $G$, which is large in $G$. By Fact 3.8, there is a collection $\{b_j \in G : j \in J\}$, with each $b_j$ definable over $A$, such that $G = \bigcup_{j \in J} b_j V$. For each $j \in J$ and $g \in \mathcal{G}$, consider the definable set $V_{j,g} := b_j U_g$ and the bijection $\psi_{j,g} : V_{j,g} \rightarrow U_g : y \mapsto b_j^{-1} y$. Finally, it is easy to check that $\{(V_{j,g}, \psi_{j,g})\}_{j \in J, g \in \mathcal{G}}$ is an atlas of $G$ and therefore $G$ is an ld-group over $A$.

(ii) It is clear that if $X \subset G$ is a definable subset over $C$ then it is a definable subset of $R^n$ over $C$. So, let $X$ be a definable subset of $R^n$ over $C$ and consider the atlas $\{(V_{j,g}, \psi_{j,g})\}_{j \in J, g \in \mathcal{G}}$ of $G$ constructed in the proof of (i). Since $X$ is definable over $C$ we have that $\psi_{j,g}(X \cap V_{j,g}) = b_j^{-1} X \cap U_g$ is also definable over $C$ for every $j \in J$ and $g \in \mathcal{G}$. Hence, it is enough to show that $X$ is contained in a finite union of the sets $V_{j,g}$ (which are defined over $A$) and this is clear by saturation since they cover $G$.

(iii) Let $X$ be a definable subspace of $G$ over $C$ and write $G = \bigcup_{i \in I} X_i$. By (ii) $X$ is a definable subset of $R^n$ over $C$. We will show that $\overline{X}$ is a definable subset of $R^n$ over $C$ (this is enough also by (ii)). Fix a generic point $g$ of $G$ and let $U_g$ as in Lemma 3.7. Firstly, let us show that $\overline{X} \subset X_j$ for some $j \in I$. Since $\{X_i\}_{i \in I}$ is a directed family and $X$ and $U_g$ are definable, there is $j \in I$ such that $X U_g^{-1} g \subset X_j$. Now, if $y \in \overline{X}$ then $y g^{-1} U_g \cap X \neq \emptyset$ and hence $y \in X U_g^{-1} g \subset X_j$. Finally, $\overline{X} = \{y \in X_j : g \in cl_{U_g}(gy^{-1} X \cap U_g)\}$ is clearly a definable subset of $R^n$ over $C$, where $cl_{U_g}(\cdot)$ denotes the closure in $U_g$ with respect to the inherited topology from the ambient space $R^n$. 

Theorem 3.9.(iii) states that in a $\forall$-definable group we have a good relation between the topological and the definable setting as it happens with LD-
spaces (see Fact 2.7.(1)). However, as we will see not every $\bigvee$-definable group is paracompact or Lindelöf as ld-group. Firstly, let $R$ be an $\aleph_1$-saturated elementary extension of the o-minimal structure $\langle R, <, +, -, r \rangle$, $r \in R$. Consider the collection $F$ of finite subsets of $R$. Then $(G, +)$, where $G = \bigcup_{F \in F} F \subset R$ and $+$ is the usual addition, is a $\bigvee$-definable group over $\emptyset$ which is not Lindelöf as ld-group. However, $G$ is paracompact (note that the group topology of $G$ as $\bigvee$-definable group is the discrete one). Secondly, let $S$ be a real closed field such that there is no countable subset $C \subset S_+ := \{ s \in S : s > 0 \}$ with $S = \bigcup_{x \in C} (-x, x)$ (e.g. if $S$ is $\aleph_1$-saturated). Let $R$ be an $\aleph_1$-saturated elementary extension of the o-minimal structure $\langle S, <, +, -, s \rangle$, $s \in S$. Consider $(G, +)$, where $G = \bigcup_{s \in S_+} (-s, s) \subset R$ and $+$ is the usual addition. The group $(G, +)$ is a $\bigvee$-definable group over $\emptyset$ which is not Lindelöf as ld-group. Since it is connected, $(G, +)$ is not paracompact (see Fact 2.7.(2)).

In [10], M. Edmundo considers $\bigvee$-definable groups $G = \bigcup_{i \in I} X_i$ over $A$ with the restriction $|I| < \aleph_1$ (which already implies the restriction $|A| < \aleph_1$), he calls them “locally definable” groups. This restriction on the cardinality of $I$ allows Edmundo to prove results using techniques which are not available in the general setting of $\bigvee$-definable groups. As he notes the main examples of $\bigvee$-definable groups are of this form: the subgroup of a definable group generated by a definable subset and the coverings of definable groups. The restriction on the cardinality of $|I|$ of the “locally definable” groups has also the following consequences on them as ld-spaces.

**Theorem 3.10.** (i) Every “locally definable” group over $A$ with its group topology is a Lindelöf LD-group over $A$.
(ii) Moreover, every Lindelöf LD-group over $A$ is ld-isomorphic to a “locally definable” group over $A$ (considered as an LD-group by (i)).

**Proof.** (i) Let $G$ be a “locally definable” group over $A$. By Theorem 3.9.(i), $G$ is an ld-group over $A$. We first show that $G$ is Lindelöf. Recall the notation of Theorem 3.9.(i). Write $G = \bigcup_{i \in I} X_i$, with $|I| < \aleph_1$. Since $I$ is countable, to prove that $G$ is Lindelöf we can assume that the language is countable (recall that Lindelöf property is invariant under o-minimal expansions by Proposition 2.9). Now, since for each generic $g \in G$ the definable subset $U_g$ of Lemma 3.7 is definable over $A$, the collection $\{ U_g : g \in G \text{ generic} \}$ is countable. Hence, the atlas $\{(V_{j,g}, \psi_{j,g}) : j, g \in \emptyset \}$ of the proof of Theorem 3.9.(i) is also countable and so $G$ is Lindelöf. Having proved the latter, the paracompactness follows from Theorem 3.9.(iii) and Fact 2.7.

(ii) Let $G$ be a Lindelöf LD-group over $A$. Since $G$ is regular and paracompact, by Fact 2.10 and Remark 2.11 there is an ld-triangulation $f : |K| \to G$ over $A$. Moreover, we can assume that $K$ is also a locally finite generalized simplicial complex (in this case we say that $K$ is a strictly locally finite generalized simplicial complex as in [8, Def. I.4]). Indeed, the semialgebraic Triangulation theorem [8, Thm. II.4.4] is stronger than the locally definable version we have proved here: it states that given a regular and paracompact
locally semialgebraic space $M$ there is a locally semialgebraic triangulation $f : |K| \to M$ with $K$ a strictly locally finite generalized simplicial complex. However, note that we can deduce this stronger version in the locally definable setting from the semialgebraic one. For, given an LD-space $M$, by (the weaker) locally definable version of the Triangulation theorem (Fact 2.10), there is an ld-triangulation $f : |K| \to M$ with $K$ a locally finite generalized simplicial complex. Now, since $|K|$ is a regular and paracompact locally semialgebraic space, by [8, Thm. II.4.4] there is a locally semialgebraic triangulation $g : |L| \to |K|$ partitioning all the simplices of $K$ and with $L$ a strictly locally finite generalized simplicial complex $L$. Therefore, it suffices to take the ld-triangulation $f \circ g : |L| \to M$.

Now, since $G$ is an LD-group, the dimension of $K$ is finite (see Remark 3.6). Furthermore, since $G$ is Lindelöf, the admissible covering $\{S_\iota|_K(\sigma) : \sigma \in K\}$ of $|K|$ has a countable subcovering of $|K|$. From this fact we deduce that $K$ is countable. Then, since $K$ is countable, has finite dimension and is strictly locally finite, by [8, Prop.II.3.3] we can assume that the realization $|K|$ lie in $R^{2n+1}$, $n = \dim(K)$, and that the topology it inherits from $R^{2n+1}$ coincides with its topology as LD-space. Now, define in $|K|$ a group operation via the ld-isomorphism $\psi$ and the group operation of $G$. With this group operation, $|K|$ is an LD-group which we will denote by $H$. Of course, $G$ is ld-isomorphic to $H$ via $\psi$. On the other hand, we can consider $|K|$ as a “locally definable” group. For, let $\mathcal{F}$ the collection of all finite simplicial subcomplexes of $K$. Clearly, $|K| = \bigcup_{L \in \mathcal{F}} |L|$ with the group operation obtained via $\psi$ is a “locally definable” group over $A$. Indeed, since the group operation is an ld-map, its restriction to $|L_1| \times |L_2|$ is a definable map into $R^{2n+1}$ for all $L_1, L_2 \in \mathcal{F}$. Finally, since the group operation is already continuous and the topology of $|K|$ as ld-space coincides with the one inherited form $R^{2n+1}$, the “locally definable” group $|K|$ with the ld-group structure obtained in part (i) is exactly $H$.

**Corollary 3.11.** Let $G$ be a “locally definable” group over $A$. Then, there is an ld-triangulation $\psi : |K| \to G$ of $G$ over $A$ with $|K| \subset R^{2n+1}$, $n = \dim(G)$, and such that the topology of $|K|$ as LD-space coincides with the one inherited from $R^{2n+1}$. Moreover, $|K|$ with the group operation inherited from $G$ via $\psi$ is also a “locally definable” group over $A$ whose group topology equals the one inherited from $R^{2n+1}$.

Let us point out that there are important examples of $\lor$-definable groups which are not Lindelöf LD-spaces (and hence not “locally definable” groups). The group of definable homomorphisms between abelian groups were used in [17] as a tool to study interpretability problems. In particular, given to abelian definable groups $A$ and $B$ over $C$, $C \subset R$, it is proved there that the group of definable homomorphisms $\mathcal{H}(A, B)$ from $A$ to $B$ is a $\lor$-definable group over $C$ (see [17, Prop. 2.20]). Note that $\mathcal{H}(A, B)$ might not be a
“locally definable” group (see the Examples at the end of Section 3 in [17]). Nevertheless, we have the following corollary to Theorem 3.9.

**Corollary 3.12.** $\mathcal{H}(A, B)$ is an LD-group.

**Proof.** We have already seen in Theorem 3.9.(i) that $\mathcal{H}(A, B)$ is an LD-group (and hence regular). To prove paracompactness, consider its connected component $\mathcal{H}(A, B)^0$, which is a definable group by [17, Thm. 3.6]. Then, by Theorem 3.9.(ii), $\mathcal{H}(A, B)^0$ is a definable subspace of $\mathcal{H}(A, B)$. Hence, \{g$\mathcal{H}(A, B)^0 : g \in \mathcal{H}(A, B)$\} is a locally finite covering of $\mathcal{H}(A, B)$ by open definable subspaces and therefore $\mathcal{H}(A, B)$ is paracompact (see the remarks after Fact 4.2). As we will see in the next section, the notion of connectedness used in [17] for $\sqcup$-definable groups differs from the one used here. However, in this particular case, since $\mathcal{H}(A, B)^0$ is definable, both notions coincide.

Let us say some words concerning the Ind-definable groups introduced in [14]. An Ind-definable group is defined there (roughly) as a group which is an inductive limit of definable sets with the restriction of the group operation to the relevant sets definable (see [14, Def.7.1]). The dimension of the sets involved might not be bounded and hence Ind-definable groups are not in general LD-groups (see Remark 3.6). If we restrict the attention to those of bounded dimension then, it seems easy to adapt both the arguments in [17] and those of this section to Ind-definable groups.

There are pathological examples of LD-groups which are not $\sqcup$-definable groups because we do not have a restriction on the size of the parameter set. However, our aim in this section is not to get a wider class of groups to that one of $\sqcup$-definable groups, but to put the latter in its natural topological context.

### 4 Connectedness

Recall that an LD-space $M$ is connected if there is no admissible nonempty proper clopen subspace $U$ of $M$ (see Definition 2.5).

**Remark 4.1.** Let $M$ be an LD-space. Then $M$ is connected if and only if every ld-map from $M$ to a discrete ld-space is constant.

**Proof.** Suppose $M$ is connected and let $f : M \to N$ be an ld-map, where $N$ is a discrete ld-space. Since $N$ is discrete, $\{y\}$ is a clopen definable subspace of $N$ for all $y \in N$. Therefore the admissible subspace $f^{-1}(y)$ of $M$ is clopen for all $y \in N$. Hence, since $M$ is connected, $M = f^{-1}(y_0)$ for some $y_0 \in N$. To prove the right-to-left implication, suppose that $M$ is not connected. Then there are two proper clopen admissible subspaces $U_0$ and $U_1$ of $M$ such that $U_0 \cap U_1 = \emptyset$ and $U_0 \cup U_1 = M$. Finally, it suffices to consider the ld-map $f : M \to \{0, 1\}$ such that $f(x) = i$ for all $x \in U_i$. 

16
We can extend the natural concept of “path connected” for definable spaces to the locally definable ones. Specifically, we say that an admissible subspace $X$ of an ld-space $M$ is \textit{path connected} if for every $x_0, x_1 \in X$ there is an ld-path $\alpha : [0, 1] \to X$ such that $\alpha(0) = x_0$ and $\alpha(1) = x_1$. Given an ld-space $M$, the \textit{path component} of a point $x \in M$ is the set of all $y \in M$ such that there is an ld-path from $x$ to $y$.

\textbf{Fact 4.2.} [8, Prop. I.3.18] Every path connected component of an ld-space is a clopen admissible subspace.

From the above fact we deduce that a path connected component of an ld-space is a maximal connected admissible subspace, i.e., a \textit{connected component}. Note that the family of (path) connected components is locally finite (and so is an admissible covering). Hence, if the (path) connected components of an ld-space $M$ are definable subspaces then $M$ is paracompact. The following remark is also an immediate consequence of Fact 4.2.

\textbf{Remark 4.3.} Let $M$ be an ld-space. Then $M$ is connected if and only if $M$ is path connected.

Keeping in mind both the topological and definability aspects of an ld-space, a natural notion of connectedness should satisfy the conditions established in Remarks 4.1 and 4.3 above. On the other hand, different notions of connectedness have been used for $\forall$-definable groups by several authors. However, as we will see, neither of the two conditions above is satisfied by some of them. Assume that $R$ is $\aleph_1$-saturated and fix a $\forall$-definable group $G = \bigcup_{i \in I} X_i \subset R^n$ over a subset $A$ of $R$ (recall the definition of $\forall$-definable group in Subsection 3.2). Here, we say that $G$ is connected if it is so as ld-group (see Theorem 3.9). In [17], $G$ is said to be \textit{M-connected} (\textit{PS-connected}, for us) if there is no definable set $U$ in $R^n$ such that $U \cap G$ is a nonempty proper clopen subset with the group topology of $G$. In [10], $G$ is said to be connected (\textit{E-connected}, for us) if there is no definable set $U \subset G$ such that $U$ is a nonempty proper clopen subset with the group topology of $G$. Finally, in [15], $G$ is said to be connected (\textit{OP-connected}, for us) if all the $X_i$ can be chosen to be definably connected with respect to the definable subspace structure it inherits from $G$ as ld-group. Notice that in [15] the situation is simpler because $G$ is a subgroup of a definable group and hence embedded in some $R^n$, so each $X_i$ is connected with respect to the ambient $R^n$ (see Section 3.1).

For $\forall$-definable groups the relation of the above notions is as follows:

\textit{OP-connected} $\iff$ \textit{Connected} $\implies$ \textit{PS-connected} $\implies$ \textit{E-connected}.

The second and third implications are clear by definition. Furthermore, the following examples show that these implications are strict.
Example 4.4. Let \( R \) be a non archimedean real closed field. Consider the definable set \( B = \{(t, -t) \in R^2 : t \in [0, 1]\} \cup \{(t, t-2) \in R^2 : t \in [1, 2]\} \). For each \( n \in \mathbb{N} \), consider the definable set \( X_n = (\bigcup_{i=-n}^n (2i, 0) + B) \cup (\bigcup_{i=-n}^n (2i, -\frac{1}{2}) + B) \subset R^2 \). Define a group operation on \( G = \bigcup_{n \in \mathbb{N}} X_n \) via the natural bijection of \( G \) with \( \text{Fin}(\mathbb{R}) \times \mathbb{Z}/2\mathbb{Z} \), where \( \text{Fin}(\mathbb{R}) = \{x \in \mathbb{R} : |x| < n \text{ for some } n \in \mathbb{N}\} \). Then, \( G \) with this group operation is a \( \bigvee \)-definable group.

Note that the topology of \( G \) inherited from \( R^2 \) coincides with its group topology. \( G \) is not connected as an ld-space because it has two connected components. However, \( G \) is PS-connected because any definable subset of \( R^2 \) which contains one of these connected components must have a nonempty intersection with the other component.

Example 4.5. [4] Let \( R \) be a non archimedean real closed field and consider the definable sets \( X_n = (-n, -\frac{1}{n}) \cup (\frac{1}{n}, n) \) for \( n \in \mathbb{N}, n > 1 \). Then, \( G = \bigcup_{n>1} X_n \) is a \( \bigvee \)-definable group with the multiplicative operation of \( R \).

Here, again, the topology \( G \) inherits from \( R^2 \) coincides with its group topology. The \( \bigvee \)-definable group \( G \) is not PS-connected since it is the disjoint union of the clopen subsets \( \{x \in R : x > 0 \} \cap G \) and \( \{x \in R : x < 0 \} \cap G \). But neither of these subsets is definable and therefore \( G \) is E-connected.

In particular, since both PS-connectedness and E-connectedness are not equivalent to connectedness, the remarks (A) and (B) above are not true for them. We point out that even though there are pathological examples, the results in [17] are correct for PS-connectedness. For the results in [10], one should substitute E-connectedness by connectedness (see [4]).

We now prove the equivalence between OP-connectedness and connectedness.

Proposition 4.6. Let \( G \) be a \( \bigvee \)-definable group over \( A \). Then, \( G \) is OP-connected if and only if \( G \) is connected.

Proof. Firstly, recall that by Theorem 3.9 a subset of \( G \) is a definable subspace if and only if it is a definable subset of \( R^n \). Let \( G \) be an OP-connected \( \bigvee \)-definable group, i.e., such that \( G = \bigcup_{i \in I} X_i \) with \( X_i \) definably connected for all \( i \in I \). Consider a nonempty admissible clopen subspace \( U \) of \( G \). Since \( U \) is not empty and each \( X_i \) is definably connected, there is \( i_0 \in I \) such that \( X_{i_0} \subset U \). Now, for every \( i \in I \) there is \( j \in I \) with \( X_{i_0} \cup X_i \subset X_j \). Since \( X_j \) is definably connected and \( \emptyset \neq X_{i_0} \subset X_j \cap U \) we have that \( X_j \subset U \) and, in particular, \( X_i \subset U \). So we have proved that for every \( i \in I, X_i \subset U \). Hence \( U = G \), as required.

Now, let \( G \) be a connected \( \bigvee \)-definable group over \( A \). Let \( \mathcal{C} \) be the collection of all connected definable subspaces over \( A \) of \( G \) which are connected and contain the unit element of \( G \). It is enough to show that \( G = \bigcup_{X \in \mathcal{C}} X \). Note that we just consider the connected definable subspaces of \( G \) which
are definable over $A$ because we need to preserve the parameter set. So let $x \in G$. By Fact 4.2, $G$ is also path connected and hence there is an ld-curve $\alpha : I \to G$ such that $\alpha(0) = x$ and $\alpha(1) = e$. Since $\alpha(I)$ is definable and $G$ is an ld-group over $A$, a finite union of charts (which are definable over $A$) contains $\alpha(I)$. Hence $\alpha(I)$ is contained in a definable over $A$ subset $X$ of $G$. Taking the adequate connected component, we can assume that $X$ is connected. Hence $x \in X \in \mathcal{C}$.

\textbf{Corollary 4.7.} A \bigvee-definable group is OP-connected if and only if is path-connected.

\textit{Proof.} By Fact 4.2 and Proposition 4.6.

\textbf{Omitting the r.c.f. assumption 4.8.} We discuss whether or not the real closed field assumption can be weakened in the previous sections.

\textit{Section 2:} All the definitions and the results up to Proposition 2.9 included apply (with the same proofs) to any o-minimal expansion of a group, except Remark 2.6 because of the lack of Robson’s embedding lemma (see an example in [13]). Of course, the rest of the section, referring mainly to triangulations, makes nonsense in this general context.

\textit{Section 3:} As above, every goes through for o-minimal expansions of groups (with the obvious adaptation in the proof of Lemma 3.7) except when we work with triangulations, i.e., Theorem 3.10.(i) and Corollary 3.11.

\textit{Section 4:} All the results apply to any o-minimal expansion of an ordered group (with the same proofs). Note that in the examples it suffices to consider an adequate reduct.

5 Homology of locally definable spaces

We fix for the rest of this section an LD-space $M$. We consider the abelian group $S_k(M)^R$ freely generated by the \textit{singular locally definable simplices} $\sigma : \Delta_k \to M$, where $\Delta_k$ is the standard $k$-dimensional simplex in $R$. Note that since $\sigma$ is locally definable and $\Delta_k$ is definable, the image $\sigma(\Delta_k)$ is a definable subspace of $M$. As we will see, this fact allows us to use the o-minimal homology developed by A. Woerheide in [19] (see also [1] for an alternative development of simplicial o-minimal homology). The boundary operator $\partial : S_{k+1}(M)^R \to S_k(M)^R$ is defined as in the classical case, making $S_*(M)^R = \bigoplus_k S_k(M)^R$ into a chain complex. We similarly define the chain complex of a pair of locally definable spaces. The graded group $H_*(M)^R = \bigoplus_k H_k(M)^R$ is defined as the homology of the complex $S_*(M)^R$. Locally definable maps induce in a natural way homomorphisms in homology. Similarly for relative homology. Note that if $M$ is just a definable set then we obtain the usual o-minimal homology groups (see e.g. [12]).

It remains to check that the functor we have just defined satisfies the locally definable version of the Eilenberg-Steenrod axioms. We shall check
them making use of the corresponding axioms for definable sets through an adaptation of a classical result in homology that (roughly) states that the homology commutes with direct limits. Note that each definable subspace $Y \subset M$ is a definable regular space and hence affine (see Remark 2.6). Therefore, the o-minimal homology groups of $Y$ as definable set are the ones we have just defined as (locally) definable space. Denote by $\mathcal{D}_M$ the set

$$\{ Y \subset M : Y \text{ definable subspace} \}.$$  

Note that $M$ can be written as the directed union $M = \bigcup_{Y \in \mathcal{D}_M} Y$. Now, consider the direct limit

$$\lim_{\rightarrow \mathcal{Y} \in \mathcal{D}_M} H_n(Y)^R = \bigcup_{Y \in \mathcal{D}_M} H_n(Y)^R / \sim,$$

where $c_1 \sim c_2$ for $c_1 \in H_n(Y_1)^R$ and $c_2 \in H_n(Y_2)^R$, $Y_1, Y_2 \in \mathcal{D}_M$, if and only if there is $Y_3 \in \mathcal{D}_M$ with $Y_1, Y_2 \subset Y_3$ such that $(i_1)_*(c_1) = (i_2)_*(c_2)$ for $(i_1)_* : H_n(Y_1)^R \to H_n(Y_3)^R$ and $(i_2)_* : H_n(Y_2)^R \to H_n(Y_3)^R$ are the homomorphisms in homology induced by the inclusions. On the other hand, we have a well-defined homomorphism $(i_\nu)_* : H_n(Y)^R \to H_n(M)^R$ for each $Y \in \mathcal{D}_M$, where $i_\nu : Y \to M$ is the inclusion. Hence, there exists a well-defined homomorphism

$$\psi : \lim_{\rightarrow \mathcal{Y} \in \mathcal{D}_M} H_n(Y)^R \to H_n(M)^R,$$

where $\psi(\tau) = (i_\nu)_*(c)$ for $c \in H_n(Y)^R$. In a similar way, given an admissible subspace $A$ of $M$, we have a well-defined homomorphism

$$\tilde{\psi} : \lim_{\rightarrow \mathcal{Y} \in \mathcal{D}_M} H_n(Y, A \cap Y)^R \to H_n(M, A)^R,$$

where $\tilde{\psi}(\tau) = i_*(c)$ for $c \in H_n(Y, A \cap Y)^R$ and $i : (Y, Y \cap A) \to (M, A)$ the inclusion map.

**Theorem 5.1.** (i) $\psi : \lim_{\rightarrow \mathcal{Y} \in \mathcal{D}_M} H_n(Y)^R \to H_n(M)^R$ is an isomorphism. (ii) Let $A$ be an admissible subspace of $M$. Then $\tilde{\psi} : \lim_{\rightarrow \mathcal{Y} \in \mathcal{D}_M} H_n(Y, A \cap Y)^R \to H_n(M, A)^R$ is an isomorphism.

**Proof.** (i) Firstly, we show that $\psi$ is surjective. Let $c \in H_n(M)^R$ and $\alpha$ be a finite sum of singular ld-simplices of $M$ which represents $c$. Consider the definable subspace $X$ of $M$ which is the union of the images of the singular ld-simplices in $\alpha$. Hence $[\alpha] \in H_n(X)^R$ and therefore it suffices to consider $[\alpha] \in \lim_{\rightarrow \mathcal{Y} \in \mathcal{D}_M} H_n(Y)^R$. Now, let us show that $\psi$ is injective. Let $\tau \in \lim_{\rightarrow \mathcal{Y} \in \mathcal{D}_M} H_n(Y)^R$, $c \in H_n(X)^R$, $X \in \mathcal{D}_M$, such that $\psi(\tau) = 0$. Since $\psi(\tau) = 0$, there is a finite sum $\beta$ of singular ld-simplices of $M$ such that $\delta \beta = \alpha$. Consider the definable subspace $Z$ of $M$ which is the union of $X$ and the images of the singular ld-simplices in $\beta$. Then we have that $[\alpha] = 0$ in $H_n(Z)^R$ and therefore $\tau = 0$ in $\lim_{\rightarrow \mathcal{Y} \in \mathcal{D}_M} H_n(Y)^R$. The proof of (ii) is similar. \qed
Remark 5.2. Let $M$ be an LD-space and $D$ a collection of definable subspaces of $M$ such that for every $Y \in D_M$ there is $X \in D$ with $Y \subset X$. Then Theorem 5.1 remains true if we replace $D_M$ by $D$.

Now, with the above result, we verify the Eilenberg-Steenrod axioms.

Proposition 5.3 (Homotopy axiom). Let $M$ and $N$ be LD-spaces and let $A$ and $B$ be admissible subspaces of $M$ and $N$ respectively. If $f : (M, A) \to (N, B)$ and $g : (M, A) \to (N, B)$ are ld-homotopic ld-maps then $f_* = g_*$. 

Proof. Let $[\alpha] \in H_n(M, A)^R$. Consider the definable subspace $X$ of $M$ which is the union of the images of the singular ld-simplices in $\alpha$. By Theorem 5.1 and the homotopy axiom for definable sets, it is enough to prove that there is a definable subspace $Z$ of $N$ such that $f(X), g(X) \subset Z$ and that the definable maps $f|_X : (X, A \cap X) \to (Z, B \cap Z)$ and $g|_X : (X, A \cap X) \to (Z, B \cap Z)$ are definably homotopic. Let $F : (M \times I, A \times I) \to (N, B)$ be a ld-homotopy from $f$ to $g$. Then, it suffices to take $Z$ as the definable subspace $F(X \times I)$ of $N$ and the definable homotopy $F|_{X \times I} : (X \times I, A \cap X \times I) \to (Z, B \cap Z)$ from $f|_X$ to $g|_X$. 

Proposition 5.4 (Exactness axiom). Let $A$ be an admissible subspace of $M$ and let $i : (A, \emptyset) \to (M, \emptyset)$ and $j : (M, \emptyset) \to (M, A)$ be the inclusions. Then the following sequence is exact

$$\cdots \to H_n(A)^R \xrightarrow{i_*} H_n(M)^R \xrightarrow{j} H_n(M, A)^R \xrightarrow{\partial} H_{n-1}(A)^R \to \cdots,$$

where $\partial : H_n(M, A)^R \to H_{n-1}(A)^R$ is the natural boundary map, i.e, $\partial[\alpha]$ is the class of the cycle $\partial \alpha$ in $H_{n-1}(A)^R$.

Proof. It is easy to check that for every $Y \in D_M$ the following diagram commutes

$$\begin{array}{ccccccccc}
\cdots & H_n(A \cap Y) & \xrightarrow{(i_Y)_*} & H_n(Y) & \xrightarrow{(j_Y)_*} & H_n(Y, A \cap Y) & \xrightarrow{\partial} & H_{n-1}(A \cap Y) & \xrightarrow{(\iota_Y)_*} & H_{n-1}(Y) \\
\downarrow & & & & & & & & & \\
\cdots & H_n(A) & \xrightarrow{i_*} & H_n(M) & \xrightarrow{j_*} & H_n(M, A) & \xrightarrow{\partial} & H_{n-1}(A) & \xrightarrow{i_*} & H_{n-1}(M) \\
\end{array}$$

where $i_Y : (A \cap Y, \emptyset) \to (Y, \emptyset)$ and $j_Y : (Y, \emptyset) \to (Y, A \cap Y)$ are the inclusions (and the superscript $R$ has been omitted). By the o-minimal exactness axiom the first sequence is exact for every $Y \in D_M$. Hence, if we take the direct limit, the sequence remains exact. The result then follows from Theorem 5.1. 

Proposition 5.5 (Excision axiom). Let $M$ be an LD-space and let $A$ be an admissible subspace of $X$. Let $U$ be an admissible open subspace of $M$ such that $\overline{U} \subset \text{int}(A)$. Then the inclusion $j : (M - U, A - U) \to (M, A)$ induces an isomorphism $j_* : H_n(M - U, A - U)^R \to H_n(M, A)^R$. 

21
Proof. By Theorem 5.1.(ii), it is enough to prove that for each definable subspace \( Y \) of \( M \) the inclusion \( j_Y : (Y - U_Y, A_Y - U_Y) \to (Y, A_Y) \) induces an isomorphism in homology, where \( U_Y = U \cap Y \) and \( A_Y = A \cap Y \). So let \( Y \) be a definable subspace of \( M \). Since \( M \) is regular then we can regard \( Y \) as a definable set. Now, \( cl_Y(U_Y) \subset \overline{U} \cap \overline{Y} \cap Y \subset \overline{Y} \cap A \cap Y \subset int_Y(A_Y) \). Finally, by the o-minimal excision axiom, \( j_Y \) induces an isomorphism in homology.

The proof of the dimension axiom is trivial.

**Proposition 5.6** (Dimension axiom). If \( M \) is a one point set, then \( H_n(M)^R = 0 \) for all \( n > 0 \).

Once we have a well-defined homology functor in the locally definable category, we now see that this functor has a good behavior with respect to model theoretic operators. The following result will be used in Section 6 in the proof of the Hurewicz theorems for LD-spaces.

**Theorem 5.7.** The homology groups of LD-spaces are invariant under elementary extension and o-minimal expansions.

**Proof.** We prove the invariance by o-minimal expansions. So let \( R' \) be an o-minimal expansion of \( R \) and let \( M \) be an LD-space in \( R \). Denote by \( D_M \) the collection of all definable subspaces of \( M \). Recall that since \( M \) is regular each \( Y \in D_M \) can be regarded as an affine definable space (see Remark 2.6). Now, since the o-minimal homology groups are invariant under o-minimal expansions (see [6, Prop.3.2]), for each \( Y \in D_M \) there is a natural isomorphism \( F_Y : H_n(Y)^R \to H_n(Y)^{R'} \). Hence, there exist a natural isomorphism \( F : \lim_{Y \in D_M} H_n(Y)^R \to \lim_{Y \in D_M} H_n(Y)^{R'} \). On the other hand, by Theorem 5.1 and Remark 5.2 we have natural isomorphisms \( \psi_1 : \lim_{Y \in D_M} H_n(Y)^R \to H_n(M)^R \) and \( \psi_2 : \lim_{Y \in D_M} H_n(Y)^{R'} \to H_n(M)^{R'} \). Finally, we consider the natural isomorphism \( \psi_2 \circ F \circ \psi_1^{-1} : H_n(M)^R \to H_n(M)^{R'} \). The proof of the invariance by elementary extensions is similar.

**Notation 5.8.** We will denote by \( \theta \) the natural isomorphism given by Theorem 5.7 between the semialgebraic and the o-minimal homology groups of a regular and paracompact locally semialgebraic space. Note that if we restrict \( \theta \) above to the definable category then we obtain the natural isomorphism of [6, Prop.3.2].

### 6 Homotopy theory in LD-spaces

Once we have defined the category of locally definable spaces, in the following section we will develop a homotopy theory for LD-spaces, that is, regular and paracompact locally definable spaces. This section is divided in Subsections
6.1, 6.2 and 6.3, which are the locally definable analogues of Sections 3, 4 and 5 of [3], respectively.

6.1 Homotopy sets of locally definable spaces

The homotopy sets in the locally definable category are defined as in the definable one just substituting the definable maps by the locally definable ones (see Section 3 in [3]). Specifically, let \((M, A)\) and \((N, B)\) be two pairs of LD-spaces, i.e., \(M\) and \(N\) are LD-spaces and \(A\) and \(B\) are admissible subspaces of \(M\) and \(N\) respectively. Let \(C\) be a closed admissible subspace of \(M\) and let \(h : C \to N\) be an ld-map such that \(h(A \cap C) \subset B\). We say that two ld-maps \(f, g : (M, A) \to (N, B)\) with \(f|_C = g|_C = h\), are ld-homotopic relative to \(h\), denoted by \(f \sim_h g\), if there exists an ld-homotopy \(H : (M \times I, A \times I) \to (N, B)\) such that \(H(x, 0) = f(x)\), \(H(x, 1) = g(x)\) for all \(x \in M\) and \(H(x, t) = h(x)\) for all \(x \in C\) and \(t \in I\). The homotopy set of \((M, A)\) and \((N, B)\) relative to \(h\) is the set

\[\left[(M, A), (N, B)\right]_R^h = \{f : (M, A) \to (N, B)\text{ ld-map in } R, f|_C = h\}/\sim_h.\]

If \(C = \emptyset\) we omit all references to \(h\). We shall denote by \(R_0\) the field structure of the real closed field \(R\) of our o-minimal structure \(R\). Given two pairs of regular paracompact locally semialgebraic spaces \((M, A)\) and \((N, B)\) and a locally semialgebraic map \(h\) as before, note that we can consider both \([((M, A), (N, B))]_{R_0}^h\) and \([[(M, A), (N, B)]_R^h\).

The next theorem is the main result of this section and it establishes a strong relation between the locally definable and the locally semialgebraic homotopy. It is the locally definable analogue of [3, Cor.3.3]. Recall the behavior of the ld-spaces under o-minimal expansions in Proposition 2.9.

**Theorem 6.1.** Let \((M, A)\) and \((N, B)\) be two pairs of regular paracompact locally semialgebraic spaces. Let \(C\) be a closed admissible semialgebraic subspace of \(M\) and \(h : C \to N\) a locally semialgebraic map such that \(h(A \cap C) \subset B\). Suppose \(A\) is closed in \(M\). Then, the map

\[\rho : [(M, A), (N, B)]_{R_0}^h \to [(M, A), (N, B)]_R^h, \quad [f] \mapsto [f],\]

which sends the locally semialgebraic homotopic class of a locally semialgebraic map to its locally definable homotopic class, is a bijection.

An important tool for the proof of the above theorem (and in general, for the study of homotopy properties of LD-spaces) is the following homotopy extension lemma. Even though the proof for locally semialgebraic spaces (see [8, Cor.III.1.4]) can be adapted to the locally definable setting, we have included here an alternative proof which, in particular, does not make use of the Triangulation Theorem of LD-spaces (see Fact 2.10). Firstly, we prove
a technical lemma which establishes a gluing principle of ld-maps by closed definable subsets.

**Fact 6.2.** [8, Prop. I.3.16] Let $M$ be an ld-space and $\{C_j : j \in J\}$ be an admissible covering of $M$ by closed definable subspaces. Let $N$ be an ld-space and $f : M \to N$ be a map (not necessarily continuous) such that $f|_{C_j}$ is an ld-map for each $j \in J$. Then, $f$ is an ld-map.

**Proof.** Let $(M_i, \phi_i)_{i \in I}$ be the atlas of $M$. We have to prove that the conditions of Definition 2.4 are satisfied. Firstly, note that since the covering $\{C_j : j \in J\}$ is admissible, for each $i \in I$ there is a finite subset $J_i \subset J$ such that $M_i \subset \bigcup_{j \in J_i} C_j$. Therefore, since $f|M_i \cap C_j$ is continuous and $M_i \cap C_j$ is a closed subset of $M_i$ for all $j \in J_i$, $f|M_i$ is also continuous for every $i \in I$. Now, to prove that $f(M_i)$ is a definable subspace of $N$ for each $i \in I$, note that, since each $f|_{C_j}$ is an ld-map and $C_j$ is a definable subspace of $M$, $f(M_i \cap C_j)$ is a definable subspace of $N$ for all $i \in I$ and $j \in J_i$. Hence, $N_i := f(M_i) = \bigcup_{j \in J_i} f(M_i \cap C_j)$ is a definable subspace of $N$ for each $i \in I$.

Finally, the map $f|_{M_i} : M_i \to N_i$ is definable since $f|M_i \cap C_j : M_i \cap C_j \to N_i$ is definable for all $j \in J_i$.

**Lemma 6.3 (Homotopy extension lemma).** Let $M, N$ be two LD-spaces and let $A$ be a closed admissible subspace of $M$. Let $f : M \to N$ be an ld-map and $H : A \times I \to N$ a ld-homotopy such that $H(x, 0) = f(x)$ for all $x \in A$. Then, there exists a ld-homotopy $G : M \times I \to N$ such that $G(x, 0) = f(x)$ for all $x \in M$ and $G|_{AXI} = H$.

**Proof.** Without loss of generality, we can assume that $M$ is connected and hence, by Fact 2.7.(2), that $M$ is Lindelöf. Let $(M_k, \phi_k)_{k \in \mathbb{N}}$ be an atlas of $M$. Consider $X_n := \bigcup_{k=0}^n M_k$ for each $n \in \mathbb{N}$. By Fact 2.7.(1) each $X_n$ is a closed definable subspace of $M$ and hence $\{X_n : n \in \mathbb{N}\}$ is an admissible covering by closed definable subspaces such that $X_n \subset X_{n+1}$ for all $n \in \mathbb{N}$. Take the restrictions $f_n := f|_{X_n}$ and $H_n := H|_{A_n \times I}$, where $A_n$ is the closed definable subspace $A \cap X_n$. Moreover, since $M$ is regular, we can regard each $X_n$ as an affine definable space (see Remark 2.6). Now, by the o-minimal homotopy extension lemma (Lemma 2.1 in [3]) and applying an induction process, we can find a collection of definable homotopies $G_n : X_n \times I \to N$ such that $G_n(x, 0) = f_n(x)$ for all $x \in X_n$, $G_n|_{X_{n-1} \times I} = G_{n-1}$ and $G_n|_{A_n \times I} = H_n$.

Finally, we define the map $G : M \times I \to N$ such that $G|_{X_n \times I} = G_n$ for every $n \in \mathbb{N}$. By Fact 6.2, the map $G$ is locally definable and, by definition, $G|_{AXI} = H$ and $G(x, 0) = f(x)$ for all $x \in M$.

**Proof of Theorem 6.1.** With the above tools at hand we can follow the lines of the proof of [8, Thm. III.4.2]. Here are the details. As in the definable case, it suffices to prove that $p$ is surjective when $A = B = \emptyset$. Indeed, we can do here similar reductions than the ones we followed after [3, Prop. 3.2] just applying the homotopy extension lemma for LD-spaces (see Lemma 6.3).
By Fact 6.2, it suffices to show that the restriction $G_{x,t}$ is a locally semialgebraic map with $\rho_i : G_{x,t} \to H_{x,t}$ for all $x \in C \cap Y_0$ and $t \in I$. Moreover, by Lemma 6.3, there exist an ld-homotopy $H^i : M \times I \to N$ such that $H^i(x,0) = f(x)$ for all $x \in M$, $H^i(x,t) = h(x)$ for all $x \in C$ and $t \in I$ and $H^i(-,1) : M \to N$ is a locally semialgebraic map. Hence, it suffices to consider the definable homotopy $H = i \circ H^i$ where $i : N' \to N$ is the inclusion, to get $\rho_i := [H]$. General Case: Let $f : M \to N$ be an ld-map such that $f|_C = h$. We have to show that $f$ is ld-homotopic relative to $h$ to a locally semialgebraic map. Without loss of generality, we can assume that $M$ is connected and hence, by Fact 2.7.(2), that $M$ is Lindelöf. Furthermore, by [8, Thm. I.4.11] (which states the shrinking covering property for regular paracompact locally semialgebraic spaces) there is a locally finite covering $\{X_n : n \in \mathbb{N}\}$ of $M$ by closed semialgebraic subspaces. Consider the closed semialgebraic subspace $Y_n := X_0 \cup \cdots \cup X_n$ and the closed admissible subspace $C_n := Y_n \cup C$ for each $n \in \mathbb{N}$. By the previous case, there exist a definable homotopy $\bar{H}_0 : Y_0 \times I \to N$ such that $\bar{H}_0(x,0) = f(x)$ for all $x \in Y_0$, $\bar{H}_0(-,1) : Y_0 \to N$ is a locally semialgebraic map and $\bar{H}_0(x,t) = h(x)$ for all $x \in C \cap Y_0$ and $t \in I$. Moreover, by Lemma 6.3, there exist an ld-homotopy $H_0 : M \times I \to N$ with $H_0(x,0) = f(x)$ for all $x \in M$, $H_0(x,t) = h(x)$ for all $x \in C$ and $t \in I$ and such that $H_0|_{Y_0 \times I} = \bar{H}_0$. In particular, $g_0 := H_0|_{C_0 \times \{1\}}$ is a locally semialgebraic map with $g_0|_C = h$. Now, by iteration we obtain a sequence of ld-homotopies $\{H_n : M \times I \to N : n \in \mathbb{N}\}$ such that

(i) $g_n := H_n|_{C_n \times \{1\}}$ is a locally semialgebraic map,
(ii) $H_{n+1}(x,t) = g_n(x)$ for all $(x,t) \in C_n \times I$ (so $g_{n+1}|_{C_n} = g_n$), and
(iii) $H_{n+1}|_{M \times \{0\}} = H_n|_{M \times \{1\}}$.

Note that in particular $H_n(x,t) = g_0(x) = h(x)$ for all $(x,t) \in C \times I$ and $n \in \mathbb{N}$. By Fact 6.2, the map $g : M \to N$ such that $g|_{C_n} = g_n$ for $n \in \mathbb{N}$, is a locally semialgebraic map. Let us show that $f$ is ld-homotopic to $g$ relative to $h$. The idea is to glue all the homotopies $H_n$ in a correct way. Let $t_n := 1 - 2^{-n}$ for each $n \in \mathbb{N}$. Consider the map $G : M \times I \to N$ such that (a) $G(x,t) = H_n(x, t_{n+1} - t_n)$ for all $x \in M$ and $t \in [t_n, t_{n+1}]$ and (b) $G(x,t) = g(x)$ otherwise. By construction it is clear that $G(x,t) = h(x)$ for all $(x,t) \in C \times I$. It remains to check that $G$ is indeed an ld-map.

By Fact 6.2, it suffices to show that the restriction $G|_{Y_n \times I}$ is definable for
each \( n \in \mathbb{N} \). So fix \( n \in \mathbb{N} \). By definition, \( G|_{Y_n \times [0,t_n]} \) is clearly definable. On the other hand, take \((x,t) \in Y_n \times [t_n,1]\). If \( t > t_m \) for every \( m \in \mathbb{N} \), then \( G(x,t) = g(x) \) by definition. If \( t \in [t_m,t_{m+1}] \) for some \( m \geq n \), then \( G(x,t) = H_m(x,t) = g_n(x) = g(x) \). Therefore \( G|_{Y_n \times [t_n,1]} = g|_{Y_n} \), which is also a definable map. Hence \( G|_{Y_n \times I} \) is definable, as required.

The following corollary is the analogue (and it can be proved adapting its proof) of [3, Cor.3.4] for LD-spaces. Recall the behavior of the ld-spaces under elementary extensions in Fact 2.8.

**Corollary 6.4.** Let \( M \) and \( N \) be two pairs of regular paracompact locally semialgebraic spaces defined without parameters. Then, there exist a bijection

\[
\rho : [M(\mathbb{R}), N(\mathbb{R})] \rightarrow [M, N]^\mathbb{R},
\]

where \([M(\mathbb{R}), N(\mathbb{R})]\) denotes the classical homotopy set. Moreover, if the real closed field \( \mathbb{R} \) is a field extension of \( \mathbb{R} \), then the result remains true allowing parameters from \( \mathbb{R} \).

Note that both Theorem 6.1 and Corollary 6.4 remain true for systems of LD-spaces (see [3, Cor.3.3]). Thanks to the Triangulation Theorem for LD-spaces (see Fact 2.10), we have also the following corollary (see the proof of [3, Cor.3.6], noting that the finiteness of the simplicial complexes plays an irrelevant role).

**Corollary 6.5.** Let \( M \) and \( N \) be LD-spaces defined without parameters. Then, any ld-map \( f : M \rightarrow N \) is ld-homotopic to an ld-map \( g : M \rightarrow N \) defined without parameters. If moreover \( M \) and \( N \) are locally semialgebraic spaces then \( g \) can also be taken locally semialgebraic.

### 6.2 Homotopy groups of locally definable spaces

The homotopy groups in the locally definable category are defined as in the definable setting using ld-maps instead of the definable ones (see Section 4 in [3]). Specifically, given a pointed LD-space \((M,x_0)\), i.e., \( M \) is an LD-space and \( x_0 \in M \), we define the \( n \)-homotopy group as the homotopy set \( \pi_n(M,x_0)^\mathbb{R} := [(I^n, \partial I^n), (M, x_0)]^\mathbb{R} \). We define \( \pi_0(M,x_0) \) as the collection of all connected components of \( M \) (which coincides with the collection of the path connected ones by Fact 4.2). We say that \((M,A,x_0)\) is a pointed pair of LD-spaces if \( M \) is an LD-space, \( A \) is an admissible subspace of \( M \) and \( x_0 \in A \). The relative \( n \)-homotopy group, \( n \geq 1 \), of a pointed pair \((M,A,x_0)\) of LD-spaces is the homotopy set \( \pi_n(X,A,x_0)^\mathbb{R} = [(I^n,J^{n-1}), (X, A, x_0)]^\mathbb{R} \), where \( I^{n-1} = \{(t_1, \ldots, t_n) \in I^n : t_n = 0\} \) and \( J^{n-1} = \partial I^n \setminus I^{n-1} \).

As in the definable case (see Section 4 in [3]), we can see that the homotopy groups \( \pi_n(M,x_0)^\mathbb{R} \) and \( \pi_m(M,A,x_0)^\mathbb{R} \) are indeed groups for \( n \geq 1 \).
and \( m \geq 2 \), the group operation is defined via the usual concatenation of maps. Moreover, these groups are abelian for \( n \geq 2 \) and \( m \geq 3 \). Also, given an ld-map between pointed LD-spaces (or pointed pairs of LD-spaces), we define the induced map in homotopy, as usual, by composing. The latter will be a group homomorphism in the case we have a group structure. It is easy to check that with these definitions of homotopy group and induced map, both the absolute and relative homotopy groups \( \pi_n(\cdot) \) are covariant functors.

The following three results (and their relative versions) can be deduced from Theorem 6.1 (see the proofs of [3, Thm.4.1], [3, Cor.4.3] and [3, Cor.4.4]).

**Corollary 6.6.** For every regular paracompact locally semialgebraic pointed space \((M, x_0)\) and every \( n \geq 1 \), the map \( \rho : \pi_n(M, x_0)^R_0 \to \pi_n(M, x_0)^R : [f] \mapsto [f] \), is a natural isomorphism.

**Corollary 6.7.** Let \((M, x_0)\) be a regular paracompact locally semialgebraic pointed space defined without parameters. Then, there exists a natural isomorphism between the classical homotopy group \( \pi_n(M(\mathbb{R}), x_0) \) and the homotopy group \( \pi_n(M(R), x_0)^R \) for every \( n \geq 1 \).

**Corollary 6.8.** The homotopy groups are invariants under elementary extensions and o-minimal expansions.

All the results of Section 4 in [3] remains true in the locally definable category. We recall here briefly these results.

1. **The homotopy property:** If two ld-maps are ld-homotopic then they induce the same homomorphism between the homotopy groups.

2. **The exactness property:** Given a pointed pair \((M, A, x_0)\) of LD-spaces, the following sequence is exact,

\[
\cdots \to \pi_n(A, x_0) \overset{i_n}{\to} \pi_n(M, x_0) \overset{j_n}{\to} \pi_n(M, A, x_0) \overset{\partial}{\to} \pi_{n-1}(A, x_0) \to \cdots \to \pi_0(A, x_0),
\]

where \( \partial \) is the usual boundary map \( \partial : \pi_n(M, A, x_0)^R \to \pi_{n-1}(A, x_0)^R : [f] \mapsto [f]_{|n-1} \) and \( i : (A, x_0) \to (M, x_0) \) and \( j : (M, x_0, x_0) \to (M, A, x_0) \) are the inclusions (and the superscript \( R \) has been omitted).

3. **The action of \( \pi_1 \) on \( \pi_n \):** Given a pointed LD-space \((M, x_0)\), there is an action \( \beta : \pi_1(M, x_0)^R \times \pi_n(M, x_0)^R \to \pi_n(M, x_0)^R \). In a similar way, given a pointed pair \((M, A, x_0)\) of LD-spaces, there is an action \( \beta : \pi_1(A, x_0)^R \times \pi_n(M, A, x_0)^R \to \pi_n(M, A, x_0)^R \). In the absolute (relative) case, we will denote by \( \beta_{[u]} \) the isomorphism \( \beta([u], -) : \pi_n(M, x_0)^R \to \pi_n(M, x_0)^R \) (resp. \( \beta([u], -) : \pi_n(M, A, x_0)^R \to \pi_n(M, A, x_0)^R \)) for each \([u] \in \pi_1(X, x_0)^R\) (resp. \([u] \in \pi_1(A, x_0)^R\)).

The homotopy property is clear by definition. The exactness property can be proved with a straightforward adaptation of the proof of the classical one. Alternatively, we can also transfer the classical exactness property
using the Triangulation Theorem (see Fact 2.10) and Corollary 6.6. Finally, the existence of the action of \( \pi_1 \) on \( \pi_n \) is just an application of the homotopy extension lemma (see Lemma 6.3 and [3, Prop.4.6.(3)]). Furthermore, the following technical lemma is easy to prove (see the proof of [3, Lem.4.7]).

**Lemma 6.9.** Let \((M, x_0)\) and \((N, y_0)\) two pointed LD-spaces. Let \( \psi : (M, x_0) \to (N, y_0) \) be an ld-map and let \([u] \in \pi_1(M, x_0)_{\mathcal{R}} \). Then, for all \([f] \in \pi_n(M, x_0)^{\mathcal{R}}, \psi_*([\beta_{[u]}([f])]) = \beta_{\psi_*([u])}((\psi_*([f]))) \).

The only part of Section 4 in [3] which has not an obvious extension to LD-spaces is the one which concerning fibrations. Naturally, we say that an ld-map \( p : E \to B \) between LD-spaces is a (Serre) fibration if it has the homotopy lifting property for each (resp. closed and bounded) definable sets. As in [3, Rmk. 4.8], the homotopy lifting property for closed simplices implies the homotopy lifting property for pairs of closed and bounded definable sets. Note that the restriction of a (Serre) fibration to the preimage of a definable subspace is not necessarily a definable (resp. Serre) fibration. However, the fibration property (see [3, Thm.4.9]) for LD-spaces can be proved just adapting directly the classical proof.

**Theorem 6.10 (The fibration property).** Let \( B \) and \( E \) be LD-spaces. Then, for every Serre fibration \( p : E \to B \), the induced map \( p_* : \pi_n(E, F, e_0)^{\mathcal{R}} \to \pi_n(B, b_0)^{\mathcal{R}} \) is a bijection for \( n = 1 \) and an isomorphism for all \( n \geq 2 \), where \( e_0 \in F = p^{-1}(b_0) \).

As in the definable setting (see [3, Prop.4.10]), the main examples of fibrations are the covering maps. Given two ld-spaces \( E \) and \( B \), a covering map \( p : E \to B \) is a surjective ld-map \( p \) such that there is an admissible covering \( \{U_i : i \in I\} \) of \( B \) by open definable subspaces and for each \( i \in I \) and each connected component \( V \) of \( p^{-1}(U_i) \), the restriction \( p|_V : V \to U_i \) is a locally definable homeomorphism (so in particular both \( V \) and \( p|_V \) are definable).

**Proposition 6.11.** Let \( B \) and \( E \) be LD-spaces. Then, every covering map \( p : E \to B \) is a fibration.

**Proof.** Firstly, note that coverings satisfy the unicity of liftings as in the definable case (see [12, Lem.2.5]). Indeed, given a connected LD-space \( Z \) and two ld-maps \( \tilde{f}_1, \tilde{f}_2 : Z \to E \) with \( p \circ \tilde{f}_1 = p \circ \tilde{f}_2 \) and \( \tilde{f}_1(z) = \tilde{f}_2(z) \) for some \( z \in Z \), we have that \( \tilde{f}_1 \equiv \tilde{f}_2 \). This is so because both \( \{z \in Z : \tilde{f}_1(z) = \tilde{f}_2(z)\} \) and \( \{z \in Z : \tilde{f}_1(z) \neq \tilde{f}_2(z)\} \) are clopen admissible subspaces of \( Z \). The path lifting and the homotopy lifting properties also remain true for \( p \) (see the definable case in [12, Prop.2.6] and [12, Prop.2.7]). To see this for the path lifting property take an admissible covering \( \{U_j : j \in J\} \) of \( B \) as in the definition of covering map. Let \( \gamma : I \to B \) be an ld-curve. Since \( \gamma(I) \) is a definable subspace of \( B \), we have that \( \gamma(I) \subset \bigcup_{j \in J_0} U_j \) for some finite
subset $J_0$ of $J$. Now, by the shrinking covering property of definable sets, there are $0 = s_0 < s_1 < \cdots < s_r = 1$ such that for each $i = 0, \ldots, r - 1$ we have $\gamma([s_i, s_{i+1}]) \subset U_{j(i)}$ and $\gamma(s_{i+1}) \in U_{j(i)} \cap U_{j(i+1)}$. Hence, by the unicity of liftings, it suffices to lift each $\gamma|[s_i, s_{i+1}]$ step by step using the definable homeomorphism $p|_{V_{j(i)}} : V_{j(i)} \to U_{j(i)}$ for the suitable connected component $V_{j(i)}$ of $p^{-1}(U_{j(i)})$. The proof of the homotopy lifting property is similar.

Finally, the above properties and the fact that the images of definable sets by ld-maps are definable subspaces, give us the homotopy lifting property for definable sets as in [3, Prop.4.10].

\begin{proof}
Since $p$ is a covering, $p^{-1}(b_0)$ is discrete. Hence $\pi_n(p^{-1}(b_0), e_0) = 0$ for every $n \geq 1$. Then, the result follows from Proposition 6.11 and both the exactness and the fibration properties.
\end{proof}

We end this subsection with one of the motivations for considering the locally definable category.

**Fact 6.13.** [7, Thm.5.11] Let $B$ be a connected ld-space, $b_0 \in B$ and let $L$ be a subgroup of $\pi_1(B, b_0)^{R}$. Then, there exists connected ld-space $E$ and a covering $p : E \to B$ with $p_*(\pi_1(E, e_0)^{R}) = L$ for some $e_0 \in p^{-1}(b_0)$. Moreover, if $B$ is an LD-space then $E$ is also an LD-space.

### 6.3 The Hurewicz and Whitehead theorems for locally definable spaces

We define the Hurewicz homomorphism in a similar way as in the definable case but using the homology groups developed in Section 5. We fix a generator $z_n^{R_0}$ of $H_n(I^n, \partial I^n)^{R_0}$ (recall that $H_n(I^n, \partial I^n)^{R_0} \cong \mathbb{Z}$). Let $z_n^R := \theta(z_n^{R_0})$, where $\theta$ is the natural transformation of Notation 5.8 between the (locally) semialgebraic and the (locally) definable homology groups. Given a pointed LD-space $(M, x_0)$, the **Hurewicz homomorphism**, for $n \geq 1$, is the map $h_n, R : \pi_n(M, x_0)^{R} \to H_n(M)^{R} : [f] \mapsto h_n, R([f]) = f_*(z_n^R)$, where $f_* : H_n(I^n, \partial I^n)^{R} \to H_n(M)^{R}$ denotes the map in singular homology induced by $f$. We define the relative Hurewicz homomorphism adapting in the obvious way what was done in the absolute case. It is easy to check that $h_n, R$ is a natural transformation between the functors $\pi_n(-)^{R}$ and $H_n(-)^{R}$. The following result can be easily deduced from the naturality of the isomorphisms $\rho$ and $\theta$ introduced in Corollary 6.6 and Notation 5.8 respectively (see [3, Prop.5.1]).

\[29\]
Proposition 6.14. Let \((M, x_0)\) be a pointed regular paracompact locally semialgebraic space. Then, the following diagram commutes

\[
\begin{array}{ccc}
\pi_n(M, x_0)^{\mathcal{R}_0} & \xrightarrow{h_n, \mathcal{R}_0} & H_n(M)^{\mathcal{R}_0} \\
\rho \downarrow & & \downarrow \theta \\
\pi_n(M, x_0)^{\mathcal{R}} & \xrightarrow{h_n, \mathcal{R}} & H_n(M)^{\mathcal{R}}
\end{array}
\]

for all \(n \geq 1\).

Now, the proofs in the definable setting of the Hurewicz and the Whitehead theorems (see [3, Thm.5.3] and [3, Thm.5.6]) apply for LD-spaces just using (i) the locally definable category instead of the definable one, (ii) the respective isomorphisms \(\rho\) and \(\theta\) of Theorem 6.1 and Notation 5.8 instead of the definable ones and (iii) the Triangulation Theorem for LD-spaces (see Fact 2.10). Note that in the proofs of the definable versions of the Hurewicz and Whitehead theorems, the finiteness of the simplicial complexes plays an irrelevant role. Specifically, we have the following results (recall the action \(\beta\) of \(\pi_1\) on \(\pi_n\) defined after Corollary 6.8).

Theorem 6.15 (Hurewicz theorems). Let \((M, x_0)\) be a pointed LD-space and \(n \geq 1\). Suppose that \(\pi_r(M, x_0)^{\mathcal{R}} = 0\) for every \(0 \leq r \leq n - 1\). Then, the Hurewicz homomorphism

\[h_n, \mathcal{R} : \pi_n(M, x_0)^{\mathcal{R}} \to H_n(M)^{\mathcal{R}}\]

is surjective and its kernel is the subgroup generated by \(\{\beta[u][f][f]^{-1} : [u] \in \pi_1(M, x_0)^{\mathcal{R}}, [f] \in \pi_n(M, x_0)^{\mathcal{R}}\}\). In particular, \(h_n, \mathcal{R}\) is an isomorphism for \(n \geq 2\).

Theorem 6.16 (Whitehead theorem). Let \(M\) and \(N\) be two LD-spaces. Let \(\psi : M \to N\) be an ld-map such that for some \(x_0 \in M\), \(\psi_* : \pi_n(M, x_0)^{\mathcal{R}} \to \pi_n(N, \psi(x_0))^{\mathcal{R}}\) is an isomorphism for all \(n \geq 1\). Then, \(\psi\) is an ld-homotopy equivalence.

Corollary 6.17. Let \(M\) be an LD-space and let \(x_0 \in M\). If \(\pi_n(M, x_0)^{\mathcal{R}} = 0\) for all \(n \geq 0\) then \(M\) is ld-contractible.

POSTSCRIPT. After a preliminary version of this paper was written, the preprint [18] by A. Piękosz has appeared with some related results.
