Healthy and Osteoarthritic Synovial Fibroblasts Produce a Disintegrin and Metalloproteinase with Thrombospondin Motifs 4, 5, 7, and 12

Induction by IL-1β and Fibronectin and Contribution to Cartilage Damage

Current description of osteoarthritis includes the involvement of synovial inflammation. Studies contributing to understanding the mechanisms of cross-talk and feedback among the joint tissues could be relevant to the development of therapies that block disease progression. During osteoarthritis, synovial fibroblasts exposed to anomalous mechanical forces and an inflammatory microenvironment release factors such as a disintegrin and metalloproteinase with thrombospondin motifs (ADAMTS) metalloproteinases that mediate tissue damage and perpetuate inflammation. We therefore studied the production of ADAMTS by synovial fibroblasts and their contribution to cartilage degradation. Moreover, we analyzed the implication of two mediators present in the osteoarthritic joint, IL-1β as proinflammatory cytokine, and 45-kDa fibronectin fragments as products of matrix degradation. We reported that synovial fibroblasts constitutively express and release ADAMTS 4, 5, 7, and 12. Despite the contribution of both mediators to the stimulation of Runx2 and Wnt/β-catenin signaling pathways, as well as to ADAMTS expression, promoting the degradation of aggrecan and cartilage oligomeric matrix protein from cartilage, fibronectin fragments rather than IL-1β played the major pathological role in osteoarthritis, contributing to the maintenance of the disease. Moreover, higher levels of ADAMTS 4 and 7 and a specific regulation of ADAMTS-12 were observed in osteoarthritis, suggesting them as new potential therapeutic targets. Therefore, synovial fibroblasts provide the biochemical tools to the chronicity and destruction of the osteoarthritic joints. in OA joints trigger the production of cytokines and proteinases that damage connective tissues, including the cartilage. In this sense, research on inhibitory mediators of synovial activation could identify ways to avoid the progressive cartilage degradation and functional impairment. The role of synovial fibroblasts (SFs) as active drivers of joint destruction in rheumatoid arthritis is well established, but their behavior in healthy subjects and OA patients is poorly understood. It has been described that OA-SF exposed to anomalous mechanical forces and to an inflammatory microenvironment, release factors such as a disintegrin and metalloproteinase with thrombospondin motifs (ADAMTS), that mediate tissue damage and perpetuate inflammation. Therefore, studies contributing to a better understanding of the cross-talk and feed-back mechanisms among the joint tissues could be relevant to the development of new therapies able to block disease progression.

Our aim was to elucidate the role of SF in the cartilage joint degradation in OA patients through the production of ADAMTS and to characterize these metalloproteinases in HD-SF. We have mapped the expression and function of aggreganases ADAMTS 4 and 5, which degrade aggrecan, one of the main components of the cartilage extracellular matrix (ECM) that facilitates cartilage to resist compression. We have also characterized ADAMTS 7 and 12, involved in destruction of cartilage oligomeric matrix protein (COMP), a noncollagenous component of the cartilage ECM that contributes to its assembly and to the cartilage integrity. Moreover, we studied the physiopathological effect of two mediators present in OA joint microenvironment: the catabolic cytokine IL-1β and the 45-kDa fibronectin fragments (Fn-fs) as products of cartilage ECM degradation.

Patients and Synovial Fibroblast Cultures

Synovial tissue was obtained from 20 active OA patients (16 women and 4 men) aged between 48 and 87 years, at the time of knee prosthetic replacement surgery. Patients had advanced disease and were diagnosed with primary OA, excluding trauma, inflammatory disease, and other structural causes of secondary OA. Control samples from HD were obtained from four patients (two women and two men) aged between 35 and 72 years, at the time of knee arthroscopic evaluation. These patients were diagnosed with meniscectomy caused by trauma to the knee or sports injury, excluding inflammatory and rheumatic diseases. The study was performed according to the recommendations of the Declaration of Helsinki and approved by the Clinical Research Ethics Committee of the Hospital La Princesa (Madrid, Spain). All biopsy samples were obtained after subjects gave informed consent.

SF cultures were established by explant growth of synovial biopsies, cultured in Dulbecco’s modified Eagle’s medium (DMEM) with 25 mmol/L HEPES and 4.5 g/L glucose, completed with 10% heat-inactivated fetal bovine serum (Lonza Ibérica S.A.U., Barcelona, Spain), 1% l-glutamine, and 1% antibiotic-antimycotic (Invitrogen, Carlsbad, CA) at 37°C and 5% CO₂. After three passages, residual contamination by macrophages was avoided, previously assessed by flow cytometry analysis of SF with a purity of 95%. Monocultures of SF were used for experiments until passage 8. Despite the use of cells at varying passage numbers, all comparisons within a same experimentation were made on SF at an identical passage number and at 80% to 90% confluence.

For treatments, HD- and OA-SF were cultured in serum-free DMEM with 1% l-glutamine and 1% antibiotic-antimycotic, in the absence (untreated) or presence of the following agents: 10 ng/mL IL-1β (ImmunoTools) or 10 ng/mL Fn-fs 45 kDa (Sigma-Aldrich, St Louis, MO).

RNA Extraction and Quantitative RT-PCR for ADAMTS

Gene Expression

SFs were seeded in 100-mm petri dishes (3 × 10⁵ cells per dish) and cultured in the absence or presence of 10 ng/mL IL-1β or 10 nmol/L Fn-fs 45 kDa for 24 hours. Total RNA was obtained using TriReagent (Sigma-Aldrich). Two microgram of RNA was reverse transcribed using a High Capacity cDNA Reverse Transcription Kit (Applied Biosystems, Foster City, CA). Semiquantitative real-time PCR analysis was performed using a TaqMan Gene Expression Master Mix with manufactured-predesigned primers and probes for β-actin (NM001101.3), ADAMTS-4 (NM005099.4), ADAMTS-5 (NM007038.3), ADAMTS-7 (NM014272.3), and ADAMTS-12 (NM030955.2) (Applied Biosystems). We normalized the target gene expression to the housekeeping gene, β-actin (2⁻DeltaCt). For relative quantification, results were presented as the relative expression with respect to the untreated condition using the formula 2⁻ΔΔCt, as previously described.

Quantification of ADAMTS in Culture Supernatants

SFs were seeded in 6-well plates (6 × 10⁵ cells per well) and cultured in the absence or presence of 10 ng/mL IL-1β or 10 nmol/L Fn-fs 45 kDa, for 24 hours. Levels of ADAMTS were measured in the culture supernatants using commercial enzyme-linked immunosorbent assay (ELISA) kits for
ADAMTS 4 and 5 (Cloud-Clone Corp., Houston, TX), and for ADAMTS 7 and 12 (MyBioSource, San Diego, CA).

Aggrecanase Activity Assay
SFs were seeded in 100-mm petri dishes (3 x 10^5 cells per dish) and cultured in the absence or presence of 10 ng/mL IL-1β or 10 nmol/L Fn-fs 45 kDa, for 24 hours. Aggrecanase activity was measured in the SF culture supernatants using a Sensitive Aggrecanase Activity ELISA Kit (MD Bioproducts, Zürich, Switzerland), according to the manufacturer’s instructions. Briefly, this assay consists of two modules. In the Aggrecanase Module, a modified interglobular domain (aggrecan-IGD-s) is digested with aggrecanases, and its proteolytic cleavage releases an aggrecan peptide (ARGSVIL-peptide-s), which is then quantified with antibodies in the ELISA Module.

Immunocytochemistry
SFs were seeded on glass coverslips (2.5 x 10^4 cells per glass), fixed with paraformaldehyde, and permeabilized with Tween-20 in phosphate-buffered saline. Cells were blocked with phosphate-buffered saline containing donkey anti-rabbit or mouse monoclonal anti-human antibodies and incubated with rabbit polyclonal anti-human antibodies for ADAMTS 4, 5, 7, or 12 (Sigma-Aldrich). After washing, cells were incubated with AlexaFluor 488 donkey anti-rabbit IgG antibody (Invitrogen). Coverslips were counterstained with Hoechst. Background fluorescence was reduced with Sudan Black in ethanol. Negative controls were performed in the absence of primary antibodies (data not shown). Fluorescence was examined using an Olympus BX51 microscope with DP72 camera model (objective 40x).

Runx2 Assay
SFs were seeded in 150-mm petri dishes (8 x 10^5 cells per dish). A Nuclear Extract Kit (Active Motif, Rixensart, Belgium) was used for nuclear extracts preparation, and the protein content was measured with a QuantiPro BCA Assay Kit (MD Bioproducts, Zürich, Switzerland). Cytoplasmic extracts obtained were stored at −80°C for later use in the Western blots. Nuclear extracts (12 μg per well) were added to a 96-well plate, and Runx2 activity was measured using a TransAM AML-3/Runx2 kit (Active Motif). Time course of Runx2 activation after incubation with 10 ng/mL IL-1β or 10 nmol/L Fn-fs 45 kDa was studied (data not shown), and the experiments were performed at 60 or 30 minutes of treatment, respectively.

β-Catenin Assay
To detect β-catenin levels, a β-catenin (Total) and a (Phospho) InstantOne ELISA kits were used (eBioscience, San Diego, CA) with SF cellular lysates. Briefly, SFs seeded in 100-mm petri dishes (3 x 10^5 cells per dish) were scraped into phosphate-buffered saline, centrifuged, and resuspended in the Cell Lysis Buffer Mix (eBioscience). Protein content was measured by QuantiPro BCA Assay Kit. Levels of β-catenin in the cellular lysates were measured after 60 minutes of treatment with 10 ng/mL IL-1β or 10 nmol/L Fn-fs 45 kDa.

Western Blots
For the detection of ADAMTS, SFs were seeded in 100-mm dishes and cultured to confluence. Culture supernatants were collected. For protein purification and concentration, Amicon Ultra 0.5 mL centrifugal filters (Merck Millipore, Darmstadt, Germany) were used. For Runx2 and β-catenin, the cytoplasmic extracts previously obtained were used, and protein content was measured by QuantiPro BCA Assay Kit. Cytoplasmic extracts (15 μg well) and culture supernatants were subjected to SDS-PAGE and blotted and blotted on a polyvinylidene difluoride membrane (Bio-Rad Laboratories, France).

Membranes were blocked with Tris-buffered saline containing bovine serum albumin and Tween-20, and incubated with mouse monoclonal anti-human ADAMTS-4, ADAMTS-5 (R&D Systems), Runx2, or β-catenin (Santa Cruz Biotechnology) antibodies, or rabbit polyclonal anti-human ADAMTS-7 or ADAMTS-12 antibodies (Abcam, UK). Appropriate horseradish peroxidase–conjugated secondary antibodies were applied and detected by Western blot Luminol Reagent (Santa Cruz Biotechnology). For Runx2 and β-catenin, we used β-actin as a loading control. Protein bands were scanned and quantified with the Bio-Rad Quantity One program.

Blockade Experiments
For blockade experiments, HD- and OA-SF were seeded in 100-mm dishes (3.10^5 cells per dish) and cultured in serum-free DMEM with 1% L-glutamine and 1% antibiotic-antimycotic, in the absence or presence of 10 μmol/L of MEK inhibitor, PD98059, consequently implicated in the inhibition of ERK-MAPK; 10 μmol/L of p38-MAPK inhibitor, SB203580 (Calbiochem, EMD Biosciences, San Diego, CA), or 200 ng/mL of Wnt inhibitor, DKD-1 (R&D Systems) for 1 hour. These treatments were followed by stimulation with 10 ng/mL IL-1β or 10 nmol/L Fn-fs 45 kDa, for 24 hours. Total RNA was obtained, and quantitative RT-PCR for ADAMTS 4 and 5 was performed as previously described.

GAGs and COMP Assays in Cartilage-SF Co-Cultures
Release of GAG and COMP from cartilage was measured in culture supernatants from wells containing co-cultures of SF over cartilage explants. OA human cartilages were obtained from three patients undergoing total hip arthroplasty from Hospital del Mar (Barcelona, Spain). Fixed diameter (6 mm) and height (2 mm) sections were collected from cartilage areas without macroscopic signs of OA. Samples
were frozen at −80°C and stored until testing. One explant per well was attached to a 24-well plate. HD- or OA-SF were added drop-wise on top of the cartilage surface (2 × 10⁴ SF per explant). After 3 hours of incubation, wells were filled with DMEM in the absence or presence of 10 ng/mL IL-1β or 10 nmol/L Fn-fs 45 kDa, and cultures were continued for 14 days. Culture supernatants were collected for detection of GAG and COMP, using a Blyscaen Sulfated Glycosaminoglycan Assay (Biocolor Ltd County Antrim, Ireland, UK), and a Quantikine Human COMP Immunoassay (R&D Systems, Abingdon, ON, UK), respectively. Frozen sections were prepared using a cryostat and stained with Alcian blue and Callejas’s tricromic. Sections were observed using an Olympus BX51 microscope with DP72 camera model (objective 20×).

Statistical Analysis

Data were analyzed using the GraphPad Prism software version 6. Data were subjected to normality test (Kolmogorov-Smirnov test) and equal variance test (F-test). Statistical differences between sample groups were assessed using Student’s two-tailed t-test or unpaired t-test with Welch’s correction, in case of groups with different variances. P < 0.05 was considered statistically significant. Results are presented as the means ± SEM.

Results

SFs Express and Release ADAMTS 4, 5, 7, and 12 in HD and OA Patients

We explored the constitutive expression of ADAMTS in HD- and OA-SF by quantitative RT-PCR (Figure 1). Patterns of constitutive ADAMTS gene expression were similar in untreated HD- and OA-SF: ADAMTS-5 was the most expressed followed by ADAMTS 4, 7, and 12. ADAMTS-5 transcripts were nearly 50-fold higher than ADAMTS-12. Comparing HD- and OA-SF, ADAMTS 4 and 7 transcripts were twofold and fourfold higher in OA- than in HD-SF, respectively. However, ADAMTS 5 and 12 mRNA levels were similar.

ADAMTS protein expression was confirmed by immunocytochemistry. Untreated HD- and OA-SF displayed similar morphology and both showed cytoplasmic immunostaining for ADAMTS 4, 5, 7, and 12 (Figure 2). No staining was observed in isotype controls (data not shown).
ADAMTS were also evaluated in untreated SF culture supernatants by Western blot (Figure 3). We confirmed that all ADAMTS are released to the medium by HD- and OA-SF. Western blots for ADAMTS 4 and 5 (Figure 3, A and B) revealed bands corresponding to the active forms (between 48 and 74 kDa), and additional bands with a higher molecular weight. ADAMTS-7 and ADAMTS-12 Western blots (Figure 3, C and D) showed bands with the predicted molecular weight of the enzymes (between 114 and 201 kDa), and additional smaller bands.

IL-1\(\beta\) and 45-kDa Fn-fs Enhance the Expression of ADAMTS-4 and ADAMTS-5 in SF

Because SF has been suggested to represent an important source of aggrecanases within the joint mediating cartilage destruction,\(^{10}\) we next studied the effect of IL-1\(\beta\) and Fn-fs on their production. IL-1\(\beta\) and Fn-fs increased the transcript and protein of ADAMTS-4 in HD- and OA-SF compared with the untreated cells (Figure 4, A and B). A significant increase in ADAMTS-5 transcript and protein was detected in OA-SF for both stimuli, whereas in HD stimulation was only observed in the protein after treatment with IL-1\(\beta\) (Figure 4, C and D). Altogether, these results show that IL-1\(\beta\) increased ADAMTS 4 and 5 in HD- and OA-SF, whereas Fn-fs showed more specific effects in OA, resulting in a significant augment of ADAMTS-4 in both, and in a restricted stimulation of ADAMTS-5 production in OA-SF.

Aggrecanase Activity in SF and GAGs Release in Cartilage-SF Co-Cultures

ADAMTS 4 and 5 cleave aggrecan within the interglobular domain at the Glu-373 and Ala-374 bond.\(^{21,22}\) Thus, we assessed the ability of ADAMTS 4 and 5 produced by cultured SF to this cleavage by measuring aggrecanase activation and the ARGSVL-peptide released in culture supernatants by means of ELISA. Both the constitutive aggrecanase activity (Figure 4E) and the derived peptide (data not shown) were significantly
greater in OA- compared to HD-SF. Fn-fs significantly increased aggrecanase activity (Figure 4F) and the derived peptide (data not shown) exclusively in OA-SF, whereas IL-1β did not induce any change. Interestingly, these results correlated with the Fn-fs induction of ADAMTS 4 and 5 in OA-SF.

The aggrecanase activity yields the generation of GAGs from the aggrecan in cartilage ECM. Hence, we next studied measuring GAG release in supernatants from cartilage-SF co-cultures, a mono-layer of SF was observed exclusively on the cartilage surface (Figure 4G). The effects of IL-1β and Fn-fs after 14 days of treatment were evaluated. The constitutive release of GAGs to the medium was significantly greater in OA-SF compared to HD-SF. IL-1β induced no change in GAGs levels, whereas Fn-fs enhanced significantly the release of GAGs in both HD- and OA-SF (Figure 4I).

Runx2 and β-Catenin Activation in SF

Because Runx2 transcription factor and Wnt/β-catenin signaling are involved in aggrecanase gene expression,16–18 and also seem to be implicated in the OA pathology,23,24 we decided to examine whether IL-1β or Fn-fs could alter the ADAMTS 4 and 5 expressions by the modulation of these factors.

Indeed, we found that both IL-1β and Fn-fs significantly induced nuclear activation of Runx2 in HD and OA-SF (Figure 5A), consistent with its reduction in the cytoplasm after the stimulation with both mediators (Figure 5C). Nonetheless, the data were consistent with a role for Runx2
in ADAMTS4 transcription because the transcript abundance with IL-1\(\beta\), on both HD and OA, was approximately twofold greater than in untreated controls. Furthermore, treatment with Fn-fs stimulated ADAMTS4 expression was approximately 2.5-fold in OA cells and approximately 1.3-fold in HD cells. In contrast to ADAMTS-4, ADAMTS-5 expression showed no stimulation of HD-SF by either IL-1\(\beta\) or Fn-fs, but approximately a 1.6-fold increase by both IL-1\(\beta\) and Fn-fs in OA.

In the cytoplasm, \(\beta\)-catenin is regulated by interaction with a multiprotein complex that phosphorylates it to be degraded by proteasomes. On activation of Wnt signaling, non-phosphorylated \(\beta\)-catenin is transported to the nucleus, where it couples with the complex T-cell factor/lymphoid-enhancing factor to initiate the transcription of ADAMTS 4 and 5 genes.\(^2^{5}\) We measured both \(\beta\)-catenin forms in cellular lysates of SF, where levels of phosphorylated \(\beta\)-catenin were undetectable by ELISA (data not shown). Thus, we measured the total \(\beta\)-catenin that mainly represented the active form.

The \(\beta\)-catenin content of whole cell lysates was approximately 1.5-fold higher for untreated OA-SF than untreated HD. Moreover, \(\beta\)-catenin levels increased to approximately twofold after treatment with either IL-1\(\beta\) or Fn-fs exclusively in OA (Figure 5B), which correlated with the reduction observed in cytosplasmic extracts by Western blot (Figure 5D).

To better elucidate the implication of Runx2 and \(\beta\)-catenin in the aggrecanases expression, we performed blockade experiments using inhibitors of two MAPK, ERK, and p38-MAPK, implicated in the activation of Runx2, PD98059, and SB203580, respectively. We also used an inhibitor of Wnt/\(\beta\)-catenin signaling, DDK-1. We showed that PD98059 significantly inhibited mRNA expression of ADAMTS-4 before treatment with IL-1\(\beta\) or Fn-fs, in HD- and OA-SF (Figure 6A). Moreover, PD98059 inhibited the expression of ADAMTS-5 in OA-SF after both stimuli, whereas in HD this inhibition was observed only before stimulation with IL-1\(\beta\) (Figure 6B). On the other hand, SB203580 is involved in the decrease of ADAMTS-4 mRNA expression.
stimulated by Fn-fs in both, HD- and OA-SF (Figure 6A). Regarding ADAMTS-5, SB203580 significantly inhibited its expression only in OA-SF, after both stimuli (Figure 6B). Moreover, the Wnt/β-catenin inhibitor DKK-1 significantly inhibited the expression of both, ADAMTS 4 and 5, before treatment with IL-1β or Fn-fs, exclusively in OA-SF (Figure 6, C and D).

Induction of ADAMTS-7 and ADAMTS-12 by IL-1β or 45-kDa Fn-fs in SF, and COMP Production in Cartilage-SF Co-Cultures

We further studied the effects of IL-1β and Fn-fs on the ADAMTS involved in the degradation of COMP. ADAMTS 7 and 12 share a C-terminal COMP/GEP-binding TSP domain. Their effects in OA are because of the association of this domain with COMP and its subsequent degradation.26 Significant increases in ADAMTS-7 transcript and protein were detected after IL-1β and Fn-fs stimulation (Figure 7, A and B). Regarding ADAMTS-12, we observed an increase of mRNA and protein induced by both stimuli exclusively in OA-SF (Figure 7, C and D).

The release of COMP and its degradative fragments was measured in the culture supernatants after 14 days of treatment with IL-1β and Fn-fs (Figure 7E). The constitutive release of COMP was significantly greater in OA-SF than in HD. Moreover, significant increases were detected after IL-1β and Fn-fs stimulation.
45-kDa Fn-fs for 24 hours was measured by quantitative RT-PCR, normalized to β-actin, and presented as the relative quantification with respect to the untreated cells using the formula $2^{-\Delta \Delta C_t}$ (described in Materials and Methods). Values are presented from triplicate determinations. B and D: Presence of ADAMTS 7 and 12 treatment with IL-1β or 45-kDa Fn-fs for 24 hours was determined by enzyme-linked immunosorbent assay in culture supernatants. Values are presented as the percentage of untreated cells (duplicate determinations). E: Cartilage oligomeric matrix protein (COMP) in cartilage-SF co-culture supernatants after treatment with IL-1β or 45-kDa Fn-fs for 14 days was detected by a Quantikine human COMP immunoassay. Values are presented from triplicate determinations. Dashed lines represent the untreated condition. Data are given as means ± SEM (A–E), $n = 4$ (A–D, HD); $n = 7$ (A–D, OA); $n = 3$ (E, HD and OA). *$p < 0.05$, **$p < 0.01$, and ***$p < 0.001$ treatment versus untreated; $^\dagger p < 0.05$ HD versus OA.

Discussion

ADAMTS metalloproteinases play key roles in cartilage homeostasis and in the pathogenesis of OA, where the disruption of this balance, in favor of proteolysis, leads to a pathological cartilage destruction. ADAMTS 4, 5, 7, and 12 have been implicated in the breakdown of cartilage in OA, and ADAMTS 4 and 5 degrading aggrecan, and ADAMTS 7 and 12 degrading COMP. Although their functions are well understood in cartilage, few studies have addressed the contribution of SF to their expression and release.

We showed that ADAMTS-5 was the most expressed in both HD- and OA-SF. Although ADAMTS4 gene expression was higher in OA than in HD, ADAMTS-5 mRNA expression was similar in both. Despite the fact that the levels of ADAMTS-5 are higher, differences in the ADAMTS-4 expression between HD and OA-SF seem to indicate its involvement in the OA pathology. However, lower levels of ADAMTS 4 and 5 have been reported in OA cartilage and synovium compared with non-OA tissues. Nevertheless, this discrepancy could be explained by the fact that whole synovium was used in their experiments. In addition, discordant data in the constitutive mRNA expression of ADAMTS 4 and 5 in non-OA and OA cartilage have been described, likely because of the different stages of the disease.

The complexity of ADAMTS regulation, by both pre- and post-transcriptional mechanisms, which ultimately determine the levels of secreted enzymes, has been reported. In this study, we demonstrated that both HD- and OA-SF release aggrecanases. Western blot analysis of ADAMTS 4 and 5 in SF culture supernatants revealed the presence of the active forms of both enzymes, between 48 and 74 kDa, similar to those reported in OA synovial fluids. We also observed a major band between 74 and 114 kDa, which has been described as the ADAMTS-4 proenzyme, in cartilage from OA patients, as well as in SF. Regarding ADAMTS-5, other authors have also reported a 70-kDa form of ADAMTS-5 in cartilage, as well as in SF from OA patients, that could represent different degradation fragments.

We reported that the aggrecanase activity and GAGs release are constitutively greater in OA than in HD. By contrast, no differences in the expression of aggrecanases between non-OA and OA synovium have been reported, with no data about their activity. Our results showed that IL-1β increased ADAMTS 4 and 5, with no impact in the
agregcanase activity or GAGs production. Because the protein abundance of ADAMTS-4 is apparently influenced by the transcript, in both HD and OA, whereas the protein abundance of ADAMTS-5 after stimulation with IL-1β in HD does not correlate with the transcript, it seems likely that this ADAMTS is not the main agregcanase. This fact corroborates other studies, which indicate that ADAMTS-5 mRNA levels do not correlate with the OA progression in chondrocytes, because of post-translational regulations. A recent study reported that IL-1β induced expression of ADAMTS-4 in SF but did not measure the activity. At the functional level, our results are in agreement with previous findings showing that ADAMTS 4 and 5 are not regulated by this cytokine in SF. The role of IL-1β in OA is controversial, and the implication of other mediators, as cartilage ECM degradation products, seems to be more relevant in the pathology. Despite that, the study of IL-1β, as a pleiotropic proinflammatory cytokine, also contributes to the knowledge of the mechanism involved in the disease. In addition, because synovial inflammation intensity is greater in OA initial stages, the lack of effects observed in the agregcanase activity after IL-1β stimulation could be explained by the advanced disease state of our patients. Although, after stimulation with IL-1β we observed effects in the levels of ADAMTS 4 and 5, they were not significant enough to promote their activity.

Articular cartilage matrix proteins are degraded in OA, resulting in the production of fragments with proinflammatory properties, including those of fibropectin. In chondrocytes, it has been described that the N-terminal Fn-fs 45 kDa induces matrix metalloproteinases synthesis and agregcan degradation; however, there are no data about its action in other joint cells. Herein, we describe for the first time the agregcanases induction by Fn-fs in SF. Consistent with these previous reports, we noticed that Fn-fs produced a more specific effect in OA-SF, increasing agregcanases production and activity, as well as cartilage degradation, evaluated by GAGs release from SF-cartilage co-cultures. Because ADAMTS-4 was also increased by Fn-fs in the co-cultures with HD- and OA-SF, these results again point to its main contribution to the agregcan degradation. The integrin zβ1 is one of the main receptors implicated in the function of fibropectin, being involved in the cartilage proteoglycan degradation induced by the 45-kDa Fn-fs. zβ1 integrins are also expressed in RA-SF, showing a significant increase compared with normal SF. Thus, SF from OA patients would synthetize agregcanases after 45-kDa Fn-fs stimulation through integrins engagement. Our data suggest that in stages of SF hyperplasia in OA, Fn-fs could establish a feedback loop contributing to the maintenance of cartilage erosion.

Runx2 can be predicted to promote ADAMTS 4 and 5 transcription. A recent study implicated it in the expression of ADAMTS 7 and 12 in OA cartilage also. On the other hand, Wnt/β-catenin signaling is a potent stimulator of chondrocyte matrix catabolic action triggering joint destruction, which also regulates agregcanases expression. Both signaling pathways seem to play important roles in the OA pathophysiology. We showed that IL-1β and Fn-fs induced Runx2 in HD- and OA-SF. Moreover, ERK- and p38-MAPK are implicated in the activation of Runx2 transcription factor. Blockade experiments showed that ERK-MAPK is involved in the expression of ADAMTS 4 and 5, stimulated by IL-1β or Fn-fs, in OA-SF. As both stimuli also induced the activation of Runx2 and the expression of both agregcanases in these cells, we can conclude that ERK-MAPK signaling through Runx2 is involved in the expression of ADAMTS 4 and 5 in OA. ERK-MAPK also regulates the expression of ADAMTS-4 after both stimuli in HD-SF, in correlation with the induction of ADAMTS-4 transcript and protein, as well as with the activation of Runx2. These data suggest that IL-1β and Fn-fs could control ADAMTS-4 transcription via ERK-MAPK and Runx2 also in SF from HD, by contrast to ADAMTS-5. On the other hand, p38-MAPK is only implicated in the expression of ADAMTS-4 after Fn-fs induction in HD- and OA-FLS, as well as in the induction of ADAMTS-5 exclusively in OA-SF by both stimuli.

Of interest, we detected β-catenin induction exclusively in OA-SF, which also correlates with the restricted inhibition of Wnt signaling in OA-SF, mediated by DKK-1 before stimulation by both, IL-1β or 45-kDa Fn-fs, pointing to the implication of this signaling pathway in the OA pathology. These results are in agreement with the higher expression of Wnt responsive genes, such as WISP1, in OA, which has been associated with a profibrotic and antichondrogenic OA-like phenotype. This interpretation is further supported by the finding that the Wnt7a/β-catenin pathway promotes proteosomal degradation of Sox9, thereby blocking expression of chondrogenic genes.

These results could shed some light on the understanding of how synovitis is triggered in OA, which is an issue under exploration. The disruption of the articular cartilage matrix is the most differing feature in OA, and the resulting fragments of ECM catabolism have been associated with inflammation through the triggering of Toll-like receptor signaling pathways. Both IL-1β and Fn-fs induced the expression of Toll-like receptor 2 in chondrocytes. Thus, in addition to integrins, Fn-fs, as an endogenous ligand of Toll-like receptors 2 and 4, could act through its engagement, given that both receptors are present in SF. Moreover, both stimuli induce the activation of MAPK signaling, implicated in the activation of Runx2 and other transcription factors, such as the NF-κB, which also induce the expression of Wnt. Therefore, we can hypothesize that IL-1β and 45-kDa Fn-fs induce agregcanases expression by activation of the transcription factor Runx2, mainly through the ERK-MAPK signaling. Moreover, these stimuli specifically induce the Wnt/β-catenin signaling in OA-SF, with the consequent therapeutic value. ADAMTS 7 and 12 have been detected mainly in cartilage, with an up-regulated expression of their transcripts in cartilage.
OA compared with HD. Regarding other joint tissues, ADAMTS 7 and 12 mRNA expression have been previously described in whole synovium, with similar levels in OA and HD. In the present study, we show, for the first time, that isolated SF express and release ADAMTS 7 and 12. ADAMTS-7 transcripts were higher in OA- than in HD-SF, whereas expression of ADAMTS-12 was similar in both. The higher expression of ADAMTS-7 in OA compared with HD also indicates the contribution of this ADAMTS in the OA pathology.

Our results are the first to describe the presence of ADAMTS 7 and 12 proteins in SF. Western blot of ADAMTS-7 showed a band between 114 and 201 kDa, similar to the active form previously described in a human kidney cell line. Regarding ADAMTS-12, we also reported a band between 114 and 201 kDa, equivalent to that previously reported in the same human, and a smaller band between 74 and 114 kDa that could represent the C-terminal fragment containing the TSP-1 repeats. As ADAMTS 7 and 12 are involved in the breakdown of articular cartilage, SFs represent other source of both metalloproteinases that would contribute to the maintenance of the cartilage damage. In this sense, COMP fragments have been identified in cartilage, synovial fluid, and serum from OA and rheumatoid arthritis patients. Moreover, increased levels of COMP in synovial fluid and serum are related to joint damage and progression in rheumatic diseases. Different joint tissues, such as bone, cartilage, synovium, and tendon, contain and express ADAMTS-7, which colocalizes with ADAMTS-12 and COMP in the cytoplasm of chondrocytes. Consistent with this, we reported herein that cartilage-OA-SF co-cultures constitutively release COMP to the medium at significantly higher levels than cartilage-HD-SF co-cultures.

Tumor necrosis factor-α and IL-1β increase ADAMTS 7 and 12 mRNA in cartilage explants, whereas ADAMTS-12 is not induced in human fetal fibroblasts. We report, for the first time in SF, that IL-1β and Fn-fs promoted significant increases in ADAMTS-7 transcripts and protein levels, being greater in OA- than in HD-SF. Similarly, ADAMTS-12 transcripts and protein were stimulated by IL-1β and Fn-fs specifically in OA-SF. Interestingly, ADAMTS-12 was the only ADAMTS studied exclusively induced in OA-SF. Those facts are important for the development of combined therapies on the basis of the blockade of these ADAMTS. Emergent data indicate that ADAMTS-12 has multiple functions in the inflammatory response, angiogenesis, and apoptosis. Thus, further studies are needed to clarify whether ADAMTS-12 is also involved in those functions during OA development.

Our results showed that the stimulation of COMP release by IL-1β and Fn-fs was greater in OA-SF. Because specific antibodies against ADAMTS 7 and 12 inhibited the tumor necrosis factor-α- or IL-1β–induced COMP degradation in the cartilage of OA patients, this increased release of COMP after IL-1β or Fn-fs treatment could be ascribed to the increased expression of both ADAMTS. Because, by contrast to ADAMTS-12, IL-1β and Fn-fs also induced ADAMTS-7 in HD-SF, COMP degradation may be mainly attributed to its action. Our data suggest that in the late phase of OA, IL-1β and Fn-fs may contribute to the damage of noncollagenous components of the ECM by increasing ADAMTS 7 and 12.

Our study presents two potential limitations. The in vitro model of cartilage-SF co-culture uses dead cartilage; thus, whether the same results would be obtained with SF adhered to live human OA cartilage is unknown. Besides, the medium used for all cell cultures was DMEM containing high glucose concentration. However, given that all treatments were performed with the same medium, this condition would not invalidate our results.

Overall, our data indicate that SF provides aggrecanases, ADAMTS-7, and ADAMTS-12 that contribute to the chronicity and destruction of OA joint. Although both IL-1β and Fn-fs have been described as mediators of cartilage degradation in OA, our findings indicate that despite the contribution of both mediators, they are Fn-fs rather than IL-1β, which plays the major pathological role, in agreement with recent studies. We showed that constitutive levels of ADAMTS-4, one of the main aggrecanases in cartilage destruction, were higher in OA than in HD. Interestingly, the higher levels of ADAMTS-7 in OA compared to HD, as well as the regulation of ADAMTS-12 by IL-1β and Fn-fs exclusively in SF from OA patients, suggest their potential as new therapeutic targets for the treatment of the disease. Altogether, our results point to an important contribution of SF, providing the biochemical tools, to the chronicity and destruction of the osteoarthritic affected joint.

Acknowledgments

We thank all patients and the collaborating clinicians for their participation in this study; and Dr. Mary B. Goldring (Hospital for Special Surgery, New York, NY) for contributions to the final manuscript.
